DYSOVARISM

Amenorrhea Dysmenorrhea
Menopausal Disorders

Dysovarism is caused by the dysfunction of one or more of three inter-dependent glands—the ovaries, the thyroid and the pituitary. It naturally follows that organotherapeutic treatment is most likely to prove effective if it combines extracts from the three glands in question. The formula, Thyro-Ovarian Co. (Harrower), embodies these three important ingredients. Moreover, each is a quality product, properly prepared with the question of cost the less consideration. In prescribing Thyro-Ovarian Co. (Harrower) you may rest assured that your patient is getting the best ovary-thyroid-pituitary combination that money can buy.

CONTRIBUTIONS

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this *Journal*.

COPYRIGHT Matter appearing in the *Journal* is covered by copyright under the Copyright Act of 1921, but, as a general rule, no objection will be made to the reproduction in reputable medical journals of anything in these columns, provided proper credit be given

MANUSCRIPTS: Should be typewritten, double spaced, and the *original* copy submitted to the respective Editorial Boards

ILLUSTRATIONS Will be paid for by us when satisfactory photographs or drawings are supplied by the author. Negatives are not acceptable. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct and preferably black and on glazed paper, drawings should be made in india ink on white paper. For illustrations requiring cuts the best copper plate is used and all are printed on glazed paper. The *Journal* reserves the right to return photographs which are not satisfactory. Contributors are respectfully requested to limit illustrations to such as are absolutely necessary.

REPRINTS TO CONTRIBUTORS: These may be ordered from the printers upon the form submitted with the galley proof

ADVERTISEMENTS

First advertising forms go to press thirty days in advance of the date of issue. In forwarding copy, time must be allowed for setting up and submitting proof. Advertising rates on request.

N B—We exclude from our columns all known questionable advertisements and appreciate notification from our readers relative to any misrepresentation.

CLASSIFIED ADVERTISEMENTS are payable in advance. To avoid delay in publishing, remit with order. Advertisements under the following headings cost \$2 00 for each insertion of 40 words or less, additional words 5 cents each.

At the Menopause

The distressing symptoms that so often accompany the climacteric, but more particularly the aggravated symptoms of the artificial menopause, are frequently controlled by the administration of

LUTEIN TABLETS, H. W. & D.
LUTEIN SOLUTION AMPULES, H. W. & D.

The choice of the medication depends, of course, on the judgment of the physician as to whether oral or hypodermatic administration is indicated. Both products represent the

CORPUS LUTEUM OF THE SOW

unmodified by treatment with solvents or by exposure to temperatures above animal body heat in the drying process. All separation of extraneous matter is made by mechanical means and all drying is *in vacuo*. The unaltered *corpus luteum* should, therefore, be presented in our products and clinical experience with them should demonstrate their therapeutic activity.

Ovarian dysfunction as evidenced in dysmenorrhea and amenorrhea is also an indication for Lutein medication, and if the diagnosis of such dysfunction is reasonably well established, definite therapeutic results may be expected.

WHOLE OVARY TABLETS, H. W. & D.
OVARIAN RESIDUE TABLETS, H. W. & D.

are also offered for those who prefer, for certain indications, the use of the whole gland or of the residue remaining after corpus luteum separation.

From Within

The remarkable efficacy of Guiatonic in all conditions of bronchial congestion may conceivably be attributed to its action from *within*. Assimilated by the digestive system, its active principles reach the area of congestion through the blood stream.

In Bronchitis, Bronchiectasis, Pneumonia, and all conditions of pulmonary congestion, Guiatonic is the logical adjuvant.

Guiatonic

A generous trial quantity free upon request William R Warner & Company, Ltd, Manufacturing Pharmacutists since 1856 727 King Street West, Toronto, Ontario

A palatable preparation of special salts of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. It contains no narcotics.

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

"NECHEBT"—The Patron Goddess of the King

In Pregnancy and Lactation

THERE are many reasons for the widespread use of "Ovaltine" in the diet of maternity. Physicians the world over recognize its value not only as an effective means of promoting the flow and quality of the milk of the nursing mother, but as a form of nutriment ideally adapted to prenatal requirements.

"Ovaltine" has a marked galactagogue action attributed to its richness in maltose and other food principles having specific galactagogue qualities and also to the fact that these principles are almost completely absorbed with minimum digestive disturbance. The use of "Ovaltine," commenced during the later stages of gestation and continued throughout the nursing period, materially aids in promoting the general health of the mother, enabling her to withstand the extra strain imposed upon the system.

OVALTINE

TONIC FOOD BEVERAGE

For similar reasons "Ovaltine" is a valuable adjunct to the diet during the whole period of pregnancy. It counteracts any tendency to constipation and in cases of vomiting, clinical experience has shown that it is well retained when ordinary forms of nourishment are rejected by the patient.

"Ovaltine" is taken as a delicious beverage which can be prepared at a moment's notice without bother, mess or trouble of any kind.

Comparative Sizes
of English
and American
Tablespoons

NOTHING tells more graphically the story of greater safety—the freedom from nutritional disturbances in infant feeding that goes with the use of Mead's Dextri-Maltose than the circumstances surrounding its introduction in England.

It had been used there for over three years as a carbohydrate addition to cow's milk mixtures. During this period results from its use had been quite satisfactory in England, as in America, it had been prescribed by the level tablespoonful.

After three years of good results, a prominent English pediatricist pointed out that the British tablespoon is twice the size of the American. The English level tablespoon holds $\frac{1}{2}$ oz. of Dextri-Maltose, the American $\frac{1}{4}$ oz. Where 6 American tablespoons had been prescribed in 24 hours the infant was actually taking 12 oz., in other words, instead of the usual $1\frac{1}{2}$ oz. per 24 hour period, the carbohydrate addition had been doubled to 3 ozs.

Despite the continued use of twice the usual amounts of Mead's Dextri-Maltose in England, nutritional disturbances were a rarity. It is doubtful if any other carbohydrate could have been used in such excessive quantities with equal immunity from serious results.

Royal College of Surgeons England

EXAMINATIONS IN CANADA

First Professional Examination for the Diploma of Fellow
TORONTO - JULY or AUGUST, 1929*

Arrangements have been completed by the Canadian Medical Association whereby the Royal College of Surgeons of England, will conduct in Canada the "Primary" examination in Anatomy and Physiology leading to the

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

The examinations, both written and *viva voce*, will be held by two examiners in each subject sent from England, and one assessor in each subject who is resident in Canada, but appointed for the purpose by the Royal College

A candidate for examination must deliver to the General Secretary of the Canadian Medical Association prior to April 1, 1929, for transmission to the Secretary of the Royal College of Surgeons, the following certificates

- 1 Of matriculation at a "recognized University",
- 2 Of having completed the examinations in Anatomy and Physiology for degrees in Medicine and Surgery of a "recognized University",
- 3 Of having dissected in a "recognized" Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a recognized Medical School
- 4 Of having attended in a "recognized" Medical School or Schools —
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall individually be engaged on the necessary experiments manipulations etc but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
- (e) a course of Histology

The fee for examination or re-examination shall be \$100 00

The Final Examination for the Fellowship is held only in England and candidates for admission to that examination must have passed the Primary Examination and hold the Diploma of Member of the Royal College of Surgeons of England or have held for not less than four years a degree of a "recognized University" registrable on the Medical Register of Great Britain.

'BYNIN' AMARA

Trade Mark

A Powerful Tonic and Hæmatinic

'BYNIN' AMARA, is of special value in neurasthenia, particularly when associated with low blood pressure, anæmia and atonic dyspepsia, in convalescence it gives that impetus which often enables the system to overcome the aftermath of disease and to recover completely.

'Bynin' Amara has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

COMPOSITION

Quinine Phosphate	1 1/2 gr
Iron Phosphate	2 "
Nux Vomica Alkaloids	
equal to Strychnin.	1/8 "
'Bynin' Liquid Malt	1 oz.

In bottles containing
10 fluid ounces

An Address

ON

ACUTE ARTICULAR RHEUMATISM AND OTHER MEMBERS OF THE RHEUMATIC CYCLE*

BY C P HOWARD, M.D., AND E S MILLS, M.D.

Montreal

RHEUMATIC fever, like syphilis and tuberculosis, is one of the most disabling diseases that prevails in temperate climates. Rarely do these diseases result in immediate death, but all three lead to insidious anatomical changes in the important viscera, which in the course of months or years result in more or less complete physical disability to the sufferer. Incidentally, this semi-invalidism means a great economic waste to the community from the loss of earning power of the patient, and entails a heavy burden on the hospital, which in turn calls for further state or private expenditure of money. While much has been done to combat the white plague and the venereal evil by popular campaigns, education of the public, establishment of diagnostic and therapeutic clinics, isolation hospitals, sanatoria, asylums, and homes for incurables, only a beginning has been made in the fight against rheumatic fever. It is encouraging to note that there is now "The International Committee for the Study and Control of Rheumatism," with branches in Berlin and Brussels¹. Any student of the literature will agree with the writers that since the classical article of the late R. P. Howard in Pepper's "System of Medicine"² of 1885 and Chedde's "Lectures on the Rheumatic State in Childhood"³ of 1889 there have only been three important contributions to our knowledge. These are in order of importance

first, Aschoff's⁴ description of the characteristic histological body that bears his name; secondly, the post mortem recognition of a rheumatic aortitis by Klotz⁵, Pappenheimer and von Glahn⁶, and, thirdly, the claims for a specific streptococcus by Povnton and Paine⁷, Beaton and Ainley Walker⁸, Rosenow⁹, Small and Birkhaug¹¹. This organism is supposed by some to circulate as such in the blood stream and by others to have an allergic influence on the tissues from one or more foci (Swift *et al*¹²).

It is not the purpose of this paper to discuss these points. We have merely undertaken a clinical study. For many years it has been known that acute articular rheumatism itself is possibly more frequent and certainly more severe in Montreal than in the other large medical centres of the continent of North America, though apparently not to the degree that prevails in Great Britain. Such figures as those given by James Bell¹³ in 1850 and C. P. Howard¹⁴ in 1903, and the still more elaborate study of Seegal and Seegal¹⁵ support this contention. It would appear that the same is not true of the complications of rheumatic fever which seem to be as prevalent in Toronto, Boston, Baltimore, New York, and Chicago and in many of the northern American cities as in Montreal, though in Texas and other southern states both rheumatic fever and its cardiac complications are less prevalent (cf. Stone¹⁶).

* From the medical service of the Montreal General Hospital. Given in abstract before the Association of American Physicians, Atlantic City, May, 1928.

INCIDENCE AT THE MONTREAL GENERAL HOSPITAL

During the three years 1925, 1926 and 1927 there were 4,760 admissions to the medical and paediatric clinics, of which 241 were for acute articular rheumatism or for its complications, carditis, chorea and erythema. This gives a ratio of approximately 1 in 20. In other words a little over 5 per cent of the total medical admissions were for the rheumatic state. These 241 admissions represent 226 cases and were made up as follows —

1 Acute articular rheumatism	104 admissions,	96 cases
2 Rheumatic cycle	137 admissions,	130 cases
Total	241 admissions,	226 cases

For purposes of statistical study, we will refer to the number of cases rather than to the number of admissions and will deal separately with the two groups.

Sex—There were 115 males, (58 of Group I and 57 of Group II), and 111 females (38 of Group I and 73 of Group II), an almost equal distribution of the sexes. In the general medical admissions, however, there are almost two males for one female, so it would appear that the female sex is specially susceptible to the rheumatic infection. It will be seen that this is notably true of the rheumatic cycle group, no doubt because of the greater incidence of chorea in girls.

Age—Eighty per cent of the entire series of 226 cases occurred between the 10th and 40th years in both sexes. There was a slightly greater prevalence of females in the first two decades. Our figures only confirm the observation of others that acute articular rheumatism is largely a disease of childhood and early adult life, and that it is rare at the extremes of life, twenty-five cases occurring in the first decade and only five in the seventh.

TABLE I

Age	Male	Female
1-10	10	15
10-20	23	36
20-30	26	29
30-40	33	13
40-50	16	13
50-60	4	3
60-70	3	2
	115	111

Race and Birth Place—Of the 226 cases there were 120 English Canadians and 19 French Canadians, a ratio of approximately 6 to 1,

whereas the normal ratio of admissions to the hospital is 2 to 1. The next largest group is the foreign and native born Hebrew, which includes 35 cases, this too is out of proportion to the normal ratio. The English born (20 cases), Scotch (9 cases) and Irish (7 cases) are the other large groups. The remaining sixteen cases came from the United States and various European countries.

Occupation—The school child formed the largest group comprising 62 cases, next came housewives with 39, clerks and stenographers formed the next largest group with 21 cases, but were closely followed by the day labourers, of whom there were 20 cases. Nurses formed the fifth largest group (16 cases). The occupations of the remaining 68 cases were so varied that an analysis of them would not prove of much value. Suffice it to say that in 31 instances it was of the strenuous outdoor variety (including 7 sailors) while 37 followed indoor occupations of the more sedentary variety. In short, there were only 20 labourers and 31 others a total of 51 cases whose work exposed them to changes of temperature, wetting and arduous toil. The remaining 175 cases (78 per cent) were school children, housewives, clerks, nurses, physicians, students, factory hands, waiters, etc., in whom exposure and great physical effort could play no etiological rôle.

Month of Admission—Forty-six per cent of the total admissions occurred in the first four months of the year, while the remaining 54 per cent occurred in the other eight months.

TABLE II

January	24	May	27	September	21
February	31	June	9	October	12
March	25	July	15	November	15
April	32	August	16	December	14
	112		67		62
	46.4 per cent		27.9 per cent		25.7 per cent

This prevalence during the winter months in Montreal is striking in view of the relatively dry cold that prevails. Of course, during these months the ventilation in the school-room, factory and home is not good as in many cases the windows are kept closed to economize the heat. Then, too, the child or adult often goes out into the cold street improperly clad.

Family History—In the family record of 59 patients, there was a history of heart disease, chorea or arthritis in at least one of their

parents or brothers or sisters. This gives an incidence of only 26 per cent, as compared with 35.5 per cent reported by Faulkner and White.¹⁷ We realize that either figure is a low estimate, as many cases of arthritis and even chorea in the family are soon forgotten by the patient.

Past Medical History—Sixty-seven per cent of the series of 226 patients gave a previous history of chorea (23 cases), tonsillitis (89 cases), or acute articular rheumatism (121 cases). Again this figure is probably low, as mild tonsillitis is often overlooked, and mild arthritis mistaken for growing pains, strain or injury. In addition, 34 patients, or 10 per cent of the series, gave a history of previous scarlet fever, possibly a disease related biologically to rheumatic fever.

Mode of Onset—In the acute articular rheumatism group of 96 cases the onset was sudden in 64 (66.6 per cent) and insidious in 32 (33.4 per cent). The disease was ushered in by acute tonsillitis in 37 of these (38.5 per cent). As one would expect, in the other group the common mode of onset was insidious in 99 cases (76.2 per cent) and acute in 31 (23.8 per cent). The combined figures of the entire series of 226 cases give an acute onset in 95 (42 per cent) and an insidious onset in 131 cases (58 per cent). The lesson that these figures teach is that a rheumatic infection is often insidious in its onset and by no means invariably acute.

The Arthritis—In the first group of 96 acute articular rheumatism cases there was of course an arthritis in all, with an average involvement of seven joints. It was severe in 9, moderately severe in 40, and mild in 47 patients. In the rheumatic fever group 30 patients developed arthritis after admission and while under treatment for their admission complaint. In these 30 cases there were many joints involved in six, and only a few in 24. As to the severity of the arthritis in this group, it was described as severe in two cases, moderately severe in five, and mild in the remaining twenty-three cases.

To summarize of the entire series of 226 cases, one hundred and twenty-six were admitted with arthritis or developed it under observation, an incidence of 55.7 per cent. Many of the remainder, in fact 54 patients, gave a previous history of one or more attacks of arthritis, which, added to the 126 seen by us, gives a total incidence of 180 patients, or 80 per cent of the

entire series, with an arthritis. There can be no doubt, therefore, that this is the most common of all the symptoms of a rheumatic infection.

Fibro-Myositis, or so-called muscular rheumatism, was extremely rare and was only noted twice in the combined groups.

The *subcutaneous fibroid nodules* described by Barlow¹⁸ and many of the English school as the characteristic lesion of the disease were found by us in only four cases. This low incidence can only have two explanations: first, the relatively small number (twenty-five cases) of children, in whom the nodules are most frequently seen; secondly, the lack of thorough and repeated search for the nodules by a trained observer. It is a truism that unless searched for they will be often overlooked as they are usually quite painless and are so small that an ordinary routine physical examination will fail to reveal them. Coates¹⁹ reports finding them in 18 of 23 rheumatic children, (80 per cent). They were found by us on the fingers of a sixteen-year old Russian girl, with a mild arthritis and mitral endocarditis, over the wrists and elbows in a Russian Jewess of 37, with erythema multiforme, purpura and arthralgia, on the fingers of a Canadian man of 25, with chronic rheumatic endocarditis of the mitral and aortic valves, during an acute exacerbation, and, lastly in a Roumanian Jewess of 14 years, with an extensive pericarditis, over the fingers, backs of the elbows and scalp, in her fourth admission during the year subsequent to our study.

Fever was present in 132 cases of the entire series or 58.4 per cent. It was almost invariably present in the arthritis group, being absent only four times after the patients' admission to the hospital. It was present in 32 cases of the rheumatic fever group of 130 cases, usually in association with an exacerbation of the arthritis or an acute rheumatic endocarditis. We saw no patient with hyperpyrexia during this three years study. Indeed no case had a temperature above 104 degrees and only 34 cases showed an elevation between 102 and 104 degrees. In the remaining 132 cases the range was between 99.5 and 102 degrees. In summary, therefore, 164 cases or 72.5 per cent of the entire series had slight or moderate fever and in none was hyperpyrexia present.

The Circulatory System—In the arthritis

group the pulse beat was above 100 per minute in 63, between 80 and 100 in 32, and under 80 in one. In the other group the pulse was below 80 in 7, between 80 and 100 in 54, and above 100 in 64 cases. In short, there was very little difference between the two groups, but in general it can be said that there was an acceleration of the pulse in 218 of the 226 cases (96 per cent) and it was a marked feature in 132 of the entire series (58 per cent).

Acute fibrinous or serofibrinous pericarditis occurred in 12 cases of the arthritis group and in 19 of the rheumatic cycle group, or 31 times in the whole series of 226 (13.7 per cent). The serofibrinous type was the exception and only once or twice was it of an extensive grade. The chronic adhesive type or adherent pericardium was recognized but once in the first group and seven times in the other, that is, eight times in the entire series (3.5 per cent). It was sometimes diagnosed clinically and not found post mortem, but also sometimes missed clinically and recognized post mortem. This discrepancy is due to the fact that in rheumatism the extension of the inflammation to the mediastinal tissues is not the rule, and an obliteration of the pericardial cavity alone is hard to recognize, except in the presence of a history of former acute pericarditis, a very dilated heart and some visible evidence of localized retraction of the chest wall. No doubt fluoroscopic examination for fixation of the heart in the thoracic cage and measurements of the rotation of the axis by the electrocardiogram would help in reaching a more correct diagnosis if the patient's condition would permit of these examinations. To summarize thirty-nine of 226 patients, or 17 per cent, had some form of pericarditis under observation.

Myocarditis, this much abused term, implies of course some degeneration of the heart muscle and was years ago stressed by Sturges²⁰ and Coombs.²¹ It no doubt occurs in every case of the rheumatic cycle to a greater or less extent. The finding of the Aschoff body is pathognomonic, but long before this body was known a myocardial degeneration was recognized. In our series it was present clinically in 92 cases, or 41 per cent. We accepted as clinical evidence first, dilatation of the heart to percussion and to the x-ray, second, signs of myocardial insufficiency, such as dyspnoea, oedema

or passive congestion of the lungs, liver or kidneys, and lastly the changes in the electrocardiogram, as described by Cohn and Swift,²² who found some abnormality in the tracings of thirty-five of the thirty-seven cases of rheumatic fever (95 per cent). An electrocardiogram was taken in only 25 cases of our arthritis series and in 16 of these it was reported as normal, in nine others (36 per cent) there was some characteristic abnormality. In the rheumatic cycle group of 130 cases it was recorded in 66, was considered as normal in 7, and pathological in 59 cases (90 per cent). In other words, in the entire series the electrocardiogram was studied in 91 cases and indicated pathological changes in 68 cases (75 per cent), a figure somewhat below that of Cohn and Swift. What were these abnormalities? Briefly stated they were fibrillation of the heart muscle, prolongation of the S-T interval, inversion of the T-wave in leads 1 and 2, notching of 'P' in lead 2, inversion of 'P' in lead 3, and auricular or ventricular extra systoles.

Acute or chronic endocarditis was present in 51 of the 96 cases of the arthritis series (53 per cent), and in 101 of the 130 cases of the rheumatic cycle group (78 per cent) or in the entire series of 226 cases 152 times (68 per cent). In 101 cases the mitral valve alone was involved, in 6 the aortic valve alone, in 44 the aortic and mitral valves were both involved and in two others the aortic, mitral and tricuspid valves were all three involved. The figures will show the predisposition of the mitral valve to the rheumatic virus, as it was affected either alone or in combination in 147 of the 152 cases or 96 per cent.

While the recent studies of von Glahn and Pappenheimer²³ have demonstrated, in a series of 47 consecutive cases of rheumatic cardiac disease, specific lesions of the small peripheral arterioles and capillaries in ten cases, either in the pulmonary or systemic arteries of the kidney, perineal adipose tissue, pancreas, ovary, testis, etc., yet the larger peripheral arteries do not seem specially liable to acute inflammatory disease in the acute rheumatic fever stage. No case occurred in Group 1 of our series of 96 cases. In the second group of 120 cases the clinical diagnosis of acute arteritis of the left tibial artery was made once in a male of thirty years who was suffering from a chronic rheu-

matic endocarditis of the mitral and aortic valves with an engrafted acute endocarditis. While under observation he developed severe pain and tenderness along the course of the left posterior tibial artery, but unassociated with local redness of the skin or subsequent impairment of the circulation. Unfortunately the tibial artery was not investigated at autopsy.

Two patients, both females of fifty years, revealed marked arteriosclerosis of the retinal or renal vessels, and the one case which came to autopsy showed atheroma of the abdominal aorta as well. Both patients had an associated affection of the thyroid gland in addition to a chronic rheumatic endocarditis of the mitral and aortic valves with the usual signs of cardiac failure, in the one case it was a toxic adenoma, and in the other a hyperplastic goitre. Either of these conditions might have been responsible for the arterial degeneration.

While no special histological study was made of the aorta for Aschoff bodies in the nineteen patients that came to autopsy, the pathologist did note in eight cases various grades of atheroma in the arch of the aorta or the entire length of the thoracic aorta, and in one case in the abdominal aorta. In all but one of these patients there was no evidence of arteriosclerosis elsewhere, and their ages ranged from 37 to 50 years, with an average age of 40 years and six months. Only two of these aortæ were examined histologically and both were considered after a casual routine study to show atheromatous changes. It is our intention to have all these nineteen aortæ most exhaustively investigated. Two other cases were considered clinically as having possibly dilated aortæ, but in only one case was this proved by the x-ray. Both recovered and were discharged well. Moreover, as both had aortic insufficiency, we prefer to regard them as having a dynamic dilatation of the aorta.

To summarize one patient had a possible acute arteritis, one had very marked arteriosclerosis, another had marked arteriosclerosis and atheroma of the abdominal aorta, while seven others revealed various degrees of atheroma of the thoracic aorta. Thus we have a total of 10 patients, or 45 per cent, with arterial changes, possibly due to the rheumatic infection.

The occurrence of a thrombus in one or other

of the chambers of the heart must be almost the rule in chronic rheumatic affection of the mitral valve. It was demonstrated in two patients at post-mortem, while in two others its presence was assumed because of the development of embolic phenomena in the lungs, spleen, kidney or brain. In addition to these, one male patient of 62 years had varicose veins of his legs with some thrombus formation, possibly not of rheumatic origin. However, one woman of 61 years developed a thrombophlebitis of her external jugular vein, but unfortunately no autopsy was permitted. Two others developed while under observation an acute thrombophlebitis of the femoral vein, the left being involved in a female of 41 years and the right in a male of 46 years. In both cases there were marked pain, tenderness, induration and œdema of the leg. Therefore, in at least three of the entire series (13 per cent), and possibly four (2 per cent), there was evidence of an inflammation of the veins. All writers are agreed that thrombophlebitis is an uncommon but authentic complication involving especially the veins of the neck and upper extremity. Sladen and Winternitz²² have collected twenty-six cases which developed in the course of myocardial failure from acute or chronic rheumatic carditis.

The Blood—The blood count in the arthritis group revealed no anæmia in nineteen patients, a slight anæmia (*i.e.*, between 4 million and 4.8 million red blood cells) in thirty-six, a moderate anæmia (*i.e.*, less than 4 million red cells) in twenty-four, while in seventeen there was no record. In the rheumatic fever group there was no anæmia in thirty-nine, slight anæmia in fifty-seven, moderate in fifteen, severe in one complicated case, and in eighteen cases there was no record. In general, one can say that in the rheumatic infection the blood was normal in fifty-eight patients (30.5 per cent) but revealed a slight anæmia in ninety-three (48.5 per cent), a moderate anæmia in thirty-nine others (20.5 per cent) and a severe anæmia in one case (0.5 per cent). It is evident therefore that the rheumatic virus produces soon or later an anæmia of slight or moderate degree in at least 70 per cent of cases as was emphasized by Trousseau many years ago.

In the first group the leucocytes averaged 12,800 per cmm. They were normal in fifteen cases, slightly elevated (9,500 to 10,500) in

eight patients, sometimes assigned to the salicylate therapy. Herpes zoster occurred but once.

Cerebral embolism, with a resultant hemiplegia, is one of the most distressing and disabling nervous complications. It occurred fortunately only in three cases, in all of course as a result of a rheumatic endocarditis and a subsequent loosening of a small thrombus, either from the valve itself or more probably from the left auricle. Two of the three embolisms resulted in a right sided hemiplegia and motor aphasia.

TREATMENT

All the cases were, needless to say, in bed for weeks at a time, in fact, the average hospital stay for the entire series was forty days, or practically six weeks. They all received a light diet and plenty of fluids. Salicylates, either in the form of sodium salicylate or tolysin, were administered to one hundred and thirty-three of the entire series (59 per cent) at some time during their stay. The newer preparations of silver, such as "Fulmigin" and "Septakrol," were not tried. Locally lead and opium or oil of wintergreen compresses were used during the acute stage of the arthritis. Baking was tried in the more protracted cases. In thirty-five cases (15 per cent) a tonsillectomy was performed, in the hope of eradicating the focus of infection and so preventing further attacks.

RESULTS

In the first group there were forty cases considered as cured, that is to say, with normal hearts and throats and joints. Only six were considered cured in the second group, a total then of thirty-six cured or 20 per cent. In the first group there were fifty-four cases, and in the second group ninety-one, discharged as improved, by which we mean the heart was compensated, though of course damaged, a total of one hundred and forty-five or 64 per cent. Fourteen were unimproved and usually left the hospital against advice or refused treatment, in other words, 6 per cent were unimproved on discharge. Twenty-one cases died in the second group, but not a single one of the arthritis or first group. This gives a mortality for the entire series of a little over 9 per cent.

SUMMARY

During three years at the Montreal General Hospital there were 4,760 medical and paediatric admissions, of which 241 were for acute articular rheumatism or its complications, carditis, chorea and erythema, an incidence of 5 per cent.

An arthritis occurred in 55.7 per cent, under observation, but if one includes the arthritis noted in the past medical history, it was present at some period of the disease in 80 per cent.

Of the cardiac manifestations, there was an acute or chronic endocarditis in 68 per cent, myocarditis in 41 per cent, and pericarditis in 17 per cent.

Only 4.5 per cent of the series showed definite arterial disease.

There was a slight or moderate anaemia and a leucocytosis of some degree in 70 per cent of the series.

Tonsillitis occurred in 46 per cent. Acute or chronic pleurisy was surprisingly frequent (15.3 per cent). Chorea was present in only 13.3 per cent of the series, comprising as it did but a small number of children.

Some form of erythema or purpura was noted in 9 per cent.

The average hospital stay per patient was six weeks. Twenty per cent were discharged as "cured", 64 per cent as improved, and 6 per cent as unimproved. There was a mortality of 9 per cent.

An Address

ON

UTERINE HÆMORRHAGE AND ITS TREATMENT*

BY THOMAS S CULLEN, M B,

Professor of Clinical Gynecology, Johns Hopkins University

Baltimore, Md

IN the *Journal of the American Medical Association* for May 27, 1922, I gave a bird's-eye view of the various conditions that produce uterine hæmorrhage¹ In the present paper I shall endeavour to bring the subject up to date, and also indicate the methods of treatment that have been found most satisfactory in the handling of the individual lesions

The conditions causing uterine hæmorrhage fall into two main groups (1) those dependent on recent pregnancy, and (2) those independent of recent pregnancy If we bear in mind these two, the study of uterine hæmorrhage becomes much easier

UTERINE HÆMORRHAGE DEPENDENT ON RECENT PREGNANCY

This occurs with (1) premature separation of the placenta, (2) retained membranes, (3) hydatidiform mole, (4) chorio epithelioma, (5) tubal pregnancy, and (6) pregnancy in one horn of a bicornuate uterus

Premature Separation of the Placenta—In such a case, the physician is aware that pregnancy exists, and he understands the cause of the bleeding His chief aim is to keep the patient quiet and prevent a miscarriage, if

feasible The possibility of placenta prævia is always in mind, and he will naturally be on the lookout for this condition

Retained Membranes—Here also the patient usually gives a history of pregnancy Every physician, however, encounters patients who stoutly deny the possibility of pregnancy, and do their best to mislead the physician, in order that he may innocently dilate and curette, and bring away the fetus and membranes In the typical case in which no criminal operation has been attempted, and in which the patient does her best to co-operate with the physician, there is a history of missing one or more menstrual periods, then bleeding has commenced, then a fetus has escaped with some water, and the after-birth has or has not been expelled In such cases dilatation of the cervix and gentle curetting will bring away any remaining portion of the after-birth and the diagnosis will be definitely settled by the finding of villi or shreds of villi in the tissue removed

In taking the history, one must ascertain if possible, whether or not the fetus has actually been seen If it has well and good, if not tubal pregnancy must be borne in mind because more than once the expulsion of a decidual cast from the uterus has been taken for a miscarriage, and the existing tubal pregnancy completely over-

* Read at the annual meeting of the Ontario Medical Association, May 30th, 1928

† Published synchronously with *Minnesota Medicine*

looked. This phase will be considered more in detail under tubal pregnancy.

Hydatidiform Mole—Now and again a pregnancy will apparently proceed normally for two or three months, and then there may be a little brownish discharge, or the patient may not feel particularly well. The case is watched for a month or two, when it is realized that something is radically wrong. The physician does not want to terminate a normal pregnancy, and yet he cannot afford to neglect his patient. Finally, it becomes clear that the uterus must be emptied, and he dilates the cervix and at once encounters quantities of small cysts that vary in size, and remind one of the variation in size of the individual grapes seen when a grapevine has worn out or gone to seed.

Now and then, as the uterus containing a hydatidiform mole increases in size, a multilocular cystic tumour develops on each side of the uterus. A knowledge of this fact materially aids one in making the diagnosis. These multilocular cysts are filled with relatively clear fluid. They are lined with several layers of lutein cells, and scattered throughout the stroma of the enlarged ovary are rows or clumps of these cells. I have never seen these multilocular lutein cysts except in association with a hydatidiform mole or with chorio-epithelioma. After removal of the mole, the cysts tend to disappear, and the ovary may again assume its normal size.

Dr. George Buel, resident surgeon at the Church Home and Infirmary, recently had a case of hydatid of the uterus with multilocular ovarian cysts on each side.

CASE 1

The patient, V. S., aged 20, was admitted to the Church Home and Infirmary on December 6, 1927, with the history of having missed her periods since September 7th. Five weeks before admission she began to have vaginal bleeding which never increased in amount. She later had nausea, swelling of the ankles, puffiness of the eyes, a lack of appetite, abdominal distention and frequent urination. Examination revealed a pregnancy of about four months' standing, with the patient showing signs of early toxæmia. She had a blood pressure of systolic 176, diastolic 80. After watching the patient for several days, it was felt that a therapeutic abortion was indicated. This was done on December 10th. Curettage brought away a large quantity of hydatidiform tissue. Most of the mole was removed, but, as the patient's condition was precarious, complete removal was not attempted.

She had a stormy convalescence with high temperature. When the packs were removed the remaining portion of the mole and placenta came away. On December 24th, the cervix was found in its normal position, the uterus was large and boggy, and on each side of the uterus was a mass about the size of a

grape fruit. She was seen two weeks later, and at this time there was no trace of either cyst. It is remarkable that two large ovarian cysts should shrink so markedly in the course of fourteen days and leave normal ovaries behind.

Chorio-Epithelioma—Occasionally, after a hydatidiform mole has been removed, the patient continues to bleed. Examination discloses that the uterus is enlarged, and now and then a metastasis may be noted in the vagina or elsewhere. When the process is advanced, hæmoptysis may be noted, due to metastases in the lung. After a hydatidiform mole has been removed, one is always fearful that a chorio-epithelioma may develop or may have existed prior to the removal of the mole. In some cases of chorio-epithelioma, no history of a previous mole can be elicited.

The histological pictures of hydatidiform mole and chorio-epithelioma are very much alike. The large cystic villi, the proliferation of Langhans' layer, and the marked outgrowth of the syncytium with vacuolization, are present in both cases. In order to differentiate between simple hydatidiform mole and chorio-epithelioma, it is necessary to examine a section from the wall of the uterus, and of course this is possible only after the organ has been removed. A diagnosis of chorio-epithelioma should never be made from scrapings. The finding of coagulation necrosis of the tissue lining the cavity of the uterus, when the diagnosis lies between chorio-epithelioma and hydatidiform mole, is strong presumptive evidence of malignancy, but even then it is unwise to make a positive diagnosis. One must either go ahead and remove the uterus in suspicious cases, or watch carefully for developments.

We cannot be too careful in the examination of tissue removed shortly after pregnancy. The uterine musculature just beneath the placenta in the early months of pregnancy often contains large, suspicious-looking cells, which seem to represent the normal reaction of the stroma and muscle cells to the stimulus of pregnancy. Were they to be encountered in the uterine wall in the absence of pregnancy, sarcoma would be suspected, but, occurring when early pregnancy has existed, they are normal. Bilateral multilocular corpora lutea cysts are frequently associated with chorio-epithelioma.

Tubal Pregnancy—Thirty years ago, few physicians knew anything about tubal preg-

nancy To-day, nearly all cases can be recognized when rupture occurs, and many of them are diagnosed before rupture takes place, at a time when operation can be performed with relative ease and little danger to the patient. The previous history in the majority of these cases is well known probably one pregnancy several years before and no conception since then, a period a few days or a month late, then a little bleeding more or less, but continuous, a little pain to the right or left of the uterus, and in some cases a premonition of impending danger. On pelvic examination, a small mass may be felt to one side of the uterus, and when a clot has formed in the pelvis, this may be felt breaking up under the finger, as rather firm jelly would do.

Our duty is to watch for new signs that will enable us to recognize tubal pregnancy at an early stage. In 1905, while examining a coloured woman under anæsthesia, just prior to operating, I found a small multinodular myomatous uterus and a nodule to one side of the uterus that gave a totally different sensation to the examining finger. On gentle pressure it had a velvety feel, on deep pressure it was firm. I diagnosed tubal pregnancy without reading the history, and operation disclosed an unruptured tubal pregnancy. The velvety feel² was undoubtedly due to the engorged vessels in the wall of the tube.

Years ago, I examined scrapings from a uterus in which the surface epithelium was intact, and the glands near the surface were slit-like and in their deeper portions hypertrophied. The stroma of the mucosa just beneath the surface had been converted into typical decidua. I wrote the attending physician that a pregnancy existed somewhere. He removed a large myomatous uterus which filled the abdomen, and in the right tube, which lay up under the liver, was a fetus. From the appearance of the uterine mucosa it was certain that an extra-uterine pregnancy existed somewhere. In this connection an instructive case may be cited.

CASE 2

The patient had gone over her period a few weeks and had had some bleeding. She was curetted, and microscopical examination revealed the surface epithelium intact, the glands slit-like near the surface and characteristically hypertrophied in the depth, while the stroma of the mucosa just beneath the surface had been converted into decidua. Although thickening of the tube could not be felt, even with the patient under anæsthesia, a diagnosis of unruptured tubal pregnancy

was made, and at operation, next day, a tubal pregnancy, not more than 1 cm. in diameter, was found.

On November 11, 1927, I saw a most interesting case

CASE 3

Mrs H. L. C., aged 37, had been married six months. The last period had occurred six weeks before consultation. It was of three days' duration and excessive, and from that time on there had been slight bleeding every day. On pelvic examination everything appeared normal. On November 12, 1927, at the Church Home and Infirmary, we again examined the pelvis and the structures seemed perfectly normal. We curetted and obtained nothing. It was obvious, however, that some pelvic condition was responsible for the bleeding, and as the patient lived at a distance, I felt it wise to make a small abdominal incision.

The right tube and ovary were normal, the uterus was normal. Situated in the left tube, about 4 cm. from the uterus, was a small oval thickening about 8 mm. long and 4 mm. broad (Fig. 1). By transmitted light, a little dark object was seen in the centre. The outer end of the tube beyond this was normal. We removed the outer half of the tube, leaving about 4 cm. of normal tube on the proximal side. The outer end of this was slit, making a fairly presentable fimbriated end.

The specimen was taken for examination by Dr. Streeter, the head of the Carnegie Laboratory of Embryology at Johns Hopkins, who had serial sections made (Fig. 2). The small dark mass noted was blood, and lying up against this small blood clot were the remnants of an exceedingly early pregnancy.

This is the earliest case of tubal pregnancy that I have ever seen, thickening of the uterine mucosa had not yet taken place.

In some cases the thickened uterine mucosa is expelled, and the patient, and even the physician, may conclude that a miscarriage has occurred and that all danger is over, whereas the pregnant tube is liable to rupture at any time. Everything that escapes from the uterus should be most carefully examined for the fetus. If it be found, tubal pregnancy can in the vast majority of cases be definitely excluded.

In the volumes dedicated to the late Sir William Osler on his seventieth birthday, July 12, 1919, I reported a new sign³ that may be of value in the diagnosis of some cases of tubal pregnancy, especially when the tubal bleeding has not been severe, but practically constant.

CASE 4

On March 21, 1918, there entered the Church Home and Infirmary a thin, wiry woman who appeared to be nearly sixty years of age, but who was actually only thirty-eight. She was the mother of seven children. For three weeks she had had pain in the right lower abdomen with intermittent attacks of abdominal distension. One week after the onset of the trouble the umbilical region suddenly became bluish black, although there had been no injury whatever in this region. Pelvic examination was very unsatisfactory, on account of the marked abdominal distension. At operation on March 27th, the uterus was found slightly enlarged, and to the

FIG 1—A Very Early Tubal Pregnancy

Mrs H. L. C. Church Home and Infirmary, November 12 1927. Near the middle of the left tube is an area of thickening oval in shape and just distal to this is a small dark spot. The fimbriated end of the tube is normal.

In the right lower corner is an enlargement of the thickened area in the tube. The small dark haemorrhagic area comes out clearly and a small subperitoneal cyst is seen on the surface of the thickened portion of the tube. There are also two smaller subperitoneal cysts.

For the appearance of the implantation of the ovum in the tube see Fig 2.

FIG 2—Early Pregnancy in a Fallopian Tube

Mrs H. L. C. Church Home and Infirmary, November 12 1927. Serial sections of the pregnant tube shown in Fig 1 were made by Dr. George L. Streeter, Director of the Carnegie Laboratory of Embryology of the Johns Hopkins Medical School, and Max Broedel has made a reconstructed illustration from Dr. Streeter's slides.

At the right is a cross-section of the tube near its middle. Then in successive sections come cross-sections of the fetal sac which contain blood clot and placental tissue. The embryo had evidently been absorbed. The small haemorrhagic spot noted in Fig 1, was a subperitoneal haemorrhage. The other small cysts were simple subperitoneal cysts.

At the left is normal tube again.

right of it was a freely movable mass, about 8 cm long and 5 cm broad. The bluish black appearance of the navel, unassociated with any history of injury, together with a mass to the right of the uterus, made the diagnosis of extra uterine pregnancy relatively certain, though the patient had not missed a period, and there had been no uterine bleeding.

The umbilicus itself was of a greenish hue, above it there was a faint bluish tinge, below it the bluish appearance was more intense. The bluish discolouration gradually diminished in intensity during the patient's sojourn in the hospital. The gradual changes in colour that took place in this region were suggestive of those that occur in a black eye resulting from a blow. At the operation the abdomen was found filled with dark blood, and attached to the fimbriated end of the right tube was an extra uterine pregnancy, which I was able to remove without sacrificing the tube. The patient made a good recovery.

Since that time several other cases of tubal pregnancy with this umbilical sign have been noted. It is hardly necessary to point out that a blue umbilicus does not always mean a tubal pregnancy, it merely indicates that there has been free blood in the abdomen. As the most frequent cause of free blood in the abdomen in the female is hæmorrhage from a tubal pregnancy, this umbilical sign will usually indicate an extra-uterine pregnancy with hæmorrhage.

Pregnancy in One Horn of a Bicornate Uterus—Early in my practice I saw a young woman who had missed a period and then started to bleed. On examination I found a uterus which seemed to be a little enlarged, and to one side of it was a well-defined lump. The patient's father was a physician, and after due consideration we concluded that an exploratory operation would be advisable. I made an incision about an inch long and found a bicornate uterus with pregnancy in the right horn. The patient left the hospital in a week and went on to term.

Pregnancy in one horn of a bicornate uterus is really extra-uterine, when considered in regard to the non-pregnant horn. If uterine bleeding exists when there is a tubal pregnancy, we can expect, in some cases at least, bleeding from the non-pregnant horn of a bicornate uterus when pregnancy exists in the other horn.

UTERINE HÆMORRHAGES OCCURRING INDEPENDENTLY OF RECENT PREGNANCY

These naturally fall into the following groups (1) hæmorrhage due to constitutional conditions, (2) hæmorrhage due to benign changes in the mucosa of the cervix and body of the uterus, (3) hæmorrhage due to malignant changes in the mucosa of the cervix and body

of the uterus, (4) hæmorrhage due to the presence of uterine tumours, and (5) hæmorrhage due to diseases of the adnexa.

Hæmorrhages Due to Constitutional Conditions—In cases of hæmophilia and some other diseases there may be a tendency to very profuse periods. Such hæmorrhages naturally come under the care of a physician and not the surgeon, since they are incidental to the medical condition with which they are associated. The cause of the hæmorrhage is evident, and as a rule the constitutional condition, and not the local bleeding, receives attention.

Hæmorrhages Due to Benign Changes in the Mucous Membrane of the Cervix and Body of the Uterus—These include (1) cervical polyp, (2) polyp of the endometrium, (3) hyperplasia of the endometrium, (4) an increased tendency for the mucosa of the cervix and vagina to bleed in elderly persons, and (5) endometritis, with blocking of the cervical canal in women advanced in years.

Simple polyp, no matter where situated, usually conform in histological appearance to the mucosa from which they arise. Nature tends to rid herself of the polyp, and it is gradually extruded. During this process it becomes engorged, and there may be hæmorrhage into the stroma of its tip. When the polyp is exposed and subjected to trauma, its tip may show an inflammatory reaction. Cervical polyp often bleed a little. The patient complains of a slight intermenstrual bleeding, and in cases in which the surface of the polyp is inflamed there may be a slight purulent or watery discharge.

Polyp springing from the mucosa of the body of the uterus consist of uterine mucosa which has been forced into the cavity of the uterus, forming a tongue-like projection. Some of the glands are often dilated, and the tip of the polyp may show some hæmorrhage. The centre of the base of the polyp often contains strands of non-striated muscle, which extend into it from the uterine wall. Polyp in the body of the uterus tend to produce excessive menstrual periods. There may be some slight intermenstrual bleeding as well.

In hyperplasia of the endometrium the mucosa is usually much thicker than normal. The surface may be smooth or show a tendency to be gathered into folds or polyp. The surface epithelium is, as a rule, thicker than normal, and

the epithelial cells tend to be higher and to stain more deeply than usual. Some of the glands are small and round, others are very large. The large and small glands, as has been pointed out by Emil Novak, remind one of the large and small holes in Swiss cheese. The large glands may be tortuous or spherical. Their epithelium is higher than usual, closely packed, and stains more deeply. The stroma of the mucosa is exceptionally cellular, and not infrequently nuclear figures are found in the stroma between the glands.

In no other condition of the endometrium do we, as a rule, find nuclear figures in the stroma, though they are normally present in the epithelial cells. Occasionally, large venous sinuses are found scattered throughout the stroma, sometimes partially or completely filled with organizing blood. Hyperplasia of the endometrium is invariably accompanied by profuse and prolonged menstrual periods. The condition is usually noted during the child-bearing period, but I have observed it in a girl of sixteen years, of so severe a degree that when she entered the hospital the hæmoglobin was only 30 per cent. On curettage we removed several tablespoonfuls of mucosa.

After curettage, the periods are usually relatively normal for from three to five months, and then curettage again becomes necessary. Sometimes, after four or five curettages the patient is permanently relieved of her symptoms.

Hyperplasia is one of the most frequent causes of profuse menstrual periods. There is usually no intermenstrual discharge, and on histological examination of the scrapings there is not the slightest resemblance to cancerous tissue.

Increased tendency for the mucosa of the cervix and vagina to bleed in elderly women. In some elderly women there is marked atrophy of the vagina, and the retracted cervix merges almost imperceptibly into the vaginal mucosa. In some of these cases, no matter how careful the assistant is in washing up the vagina, there is a considerable amount of hæmorrhage, blood oozing from fine points on the vulva, vagina and cervix. Any appreciable contact in such a case will tend to cause slight bleeding.

Mild endometritis, with blocking of the cervical canal in women advanced in years.—When a woman of sixty years or more says that since her menopause, ten or more years before, she has had no discharge until the last week or

two, and that this is blood-tinged and slightly irritating, we at once suspect cancer. On several occasions I have examined such patients and found the cervix normal in appearance. On curettage I have been surprised to obtain so little mucosa. Thus on microscopical examination has shown marked atrophy of the mucous membrane of the body, together with a mild infection of the endometrium. There has been a slight infection, the cervix has become occluded, the secretion has collected, and, finally, the cervix has opened up again. The occasional occurrence of these cases should not, however, lull us into a false sense of security. Every woman beyond the menopause who has bleeding should be examined, and if the cause does not then become evident, the uterus should be curetted and the scrapings examined microscopically.

Hæmorrhage Due to Malignant Changes in the Mucosa of the Cervix and of the Body of the Uterus.—These include (1) squamous celled carcinoma of the cervix, (2) adenocarcinoma of the cervix, (3) adenocarcinoma of the body of the uterus (squamous celled carcinoma of the body is rare), and (4) sarcoma of the endometrium.

The vaginal portion of the cervix is covered by squamous-celled epithelium. The cervical canal is lined with the mucosa which produces the mucous plug during pregnancy. The glands of this mucosa are of the racemose variety, and the epithelium lining them is of a very high cylindrical type. The cavity of the uterus is lined with a mucous membrane which usually varies from 2 to 4 mm in thickness. Its glands are tubular, and between them is a very unusual stroma whose cells, as we have seen, become of the decidual type when pregnancy exists inside or outside the uterus. From any of these three kinds of mucous membrane, cancer may develop. Accordingly, we have three varieties of cancer of the uterus, squamous celled carcinoma of the cervix, adenocarcinoma of the cervix, and adenocarcinoma of the body of the uterus.

Advanced carcinoma of the cervix is readily recognized as a large friable growth which too frequently involves the entire cervix and extends to the surrounding vaginal mucosa. As a result of the campaign of education waged by the American Society for the Control of Cancer and by local medical societies, patients are coming to the physician earlier and earlier, so

that cases are seen now in which the physician is by no means sure whether the cervix is cancerous or not. These patients should be sent to the hospital to have a wedge of the suspicious area cut out and examined microscopically.

Adenocarcinoma of the cervix frequently begins within the cervical canal, but if the cylindrical epithelium extends down beyond the external os, as it sometimes does, then the adenocarcinoma may be seen on vaginal examination. The diagnosis of this variety of gland cancer is sometimes difficult. It is the most malignant of all uterine cancers, and fortunately the least frequent.

Adenocarcinoma of the body of the uterus can be diagnosed with certainty only from scrapings. As a rule, the diagnosis is easy. When the operator removes a large amount of friable material with the curette, he suspects cancer, and hastens to make a microscopical examination of the sections. There is as much difference between the appearance of the normal lining of the uterus and cancerous tissue as there is between two different patterns of wall paper. The diagnosis is made from the general pattern of the growth, or from individual cell changes, or from both. Now and again several sections must be examined, and occasionally it may seem best to curette again in a month or two, and examine fresh sections. This is, however, rarely necessary.

Sarcoma of the endometrium is rare. When sarcoma is found in the uterus, it is usually in the musculature or associated with uterine myomas. When sarcoma develops in the endometrium it must of necessity arise from the stroma of the mucosa.

CASE 5

Several years ago I saw a patient who had slight uterine bleeding and a small nodule in the breast. The uterus was curetted, and while frozen sections were being made, the breast nodule, which was benign, was removed. Microscopical examination of the scrapings revealed a sarcoma. Complete hysterectomy was done at once, and on the day after operation the patient was in excellent condition, but on the second day her temperature rose to 104° F., on the third day it was again normal, and on the fourth day it rose to 105° F. Malarial organisms were found in the blood, appropriate treatment was instituted, and a normal recovery followed. This case has been reported in full by Brady.

Hæmorrhage Due to the Presence of Uterine Tumours—Tumours of the uterus are divisible into three main groups: (1) myomas, (2) adenomyomas, and (3) sarcomas.

Uterine myomas are very common. Some of them project into the cavity of the uterus. A myoma may reach large proportions without in any way influencing menstruation, but when it encroaches on the uterine cavity the periods are liable to be prolonged. A myoma, not over 2 or 3 cm. in diameter, projecting well into the cavity of the uterus, may cause such severe menstrual hæmorrhage that the patient is almost exsanguinated. In some cases the submucous myoma becomes necrotic in its more dependent parts, and causes a foul and almost continuous watery discharge from the uterus. On examination, a portion of the growth may be seen extending through the cervix. This tissue often feels soft, but on traction is found to be tough. Cancerous tissue, on the other hand, is friable. When a large submucous myoma has been expelled from the uterus it may completely fill the vagina. In such a case the cervix can be recognized as a smooth ring encircling the pedicle of the tumour.

Adenomyomas of the uterus form an interesting group of tumours. Although in a certain percentage of these cases the uterus is not enlarged, in the majority of them it is at least twice the normal size. The inner muscular layers of the uterus are transformed into a coarse, diffuse, myomatous tissue into which the uterine mucosa flows. The thickening may be limited to the anterior or posterior wall, or form a mantle around the entire uterine cavity. In time, portions of the adenomyoma may be forced to the outer surface, forming subperitoneal adenomyomas, or into the cavity, producing submucous adenomyomas. In many cases there are also a few small, discrete myomas scattered throughout the uterus. Adenomyomas generally cause a very profuse and prolonged menstruation, but no intermenstrual bleeding. At the period there may be a grinding pain in the uterus, due undoubtedly to swelling of the many areas of uterine mucosa in the diffuse growth of the uterine wall. Curettage, as a rule, yields perfectly normal mucosa. When adenomyoma exists, the uterus tends to become adherent to the surrounding structures.

Uterine sarcomas are relatively rare. In from 1 to 2 per cent they are associated with uterine myomas. Should a sarcoma develop in the endometrium, it can be diagnosed from scrapings, but in the average case it will be diagnosed

as a myoma, and its true character detected only when the abdomen is opened, or when the tumour has been cut into. Typical sarcoma on section differs markedly from myoma. It is homogeneous, pork-like, not striated, and, as a rule is easily broken up with the finger, whereas the finger makes no impression whatever on the myoma. Occasionally, portions of a sarcoma become submucous, and undergo necrosis and gradual disintegration. In such cases there is a good deal of foul vaginal discharge. Microscopical examination of pieces of the tissue will give the correct diagnosis, although the differentiation between a degenerating myoma and sarcoma is at times somewhat puzzling.

When considering uterine tumours and their differentiation from cancer, we must always remember that the two conditions are occasionally associated in the same uterus. In our series of cases⁸ we found squamous-celled carcinoma of the cervix in more than 1 per cent of myoma cases, and in nearly 2 per cent adenocarcinoma of the body of the uterus complicated the myomatous condition.

Uterine Hemorrhages Due to Diseases of the Adnexa—One of the cardinal signs in tubal pregnancy is uterine bleeding. In cases of purulent salpingitis also, uterine hæmorrhage is a common symptom. Time and again the operator is in doubt as to whether the given case is one of tubal pregnancy or pelvic inflammation. Sometimes he makes a diagnosis of pelvic infection and finds tubal pregnancy, and on the other hand he may diagnose extra-uterine pregnancy, only to find that he is dealing with pelvic infection. Fortunately, in both instances it is necessary to open the abdomen, and the temporary error in diagnosis does not in any way militate against the patient's welfare. If it were essential to make an absolute diagnosis before operation, a curettage would usually reveal decidua when a pregnancy existed, but there would be no sign of decidua in the inflammatory case.

CASE 6

On January 9, 1928, I saw, with my resident, Dr Robert L. Faulkner, at the Johns Hopkins Hospital, a patient (E. T.), who had been married ten years and who had had seven pregnancies. When I saw her she had been ill for more than two weeks. Her temperature, which had been high, had fallen to 101° F., and in the two weeks, as a result of severe bleeding, her hæmoglobin had dropped to 55 per cent.

On pelvic examination, I could feel a mass behind the uterus. The temperature indicated a pelvic inflam-

mation but the severe bleeding suggested the possibility of tubal pregnancy. At operation Dr Faulkner found a pelvic peritonitis and double pus tubes. Such free hæmorrhage with pus tubes is rather unusual. After operation there was no bleeding.

Inflammatory diseases of the ovaries are invariably secondary to and associated with salpingitis, consequently what has been said about uterine bleeding associated with pus tubes applies to inflammation of the ovary.

Ovarian cysts and ovarian tumours occasionally cause slight uterine bleeding. The presence of the tumour, when found to be independent of the uterus, usually gives us the clue as to the hæmorrhage, and with the removal of the ovarian growth the bleeding ceases. It is always well, however, to examine the uterus carefully if the bleeding has been severe. One of our patients who had been bleeding severely had not only a large ovarian tumour with a twisted pedicle, but also a carcinoma of the body of the uterus. When considering the diagnosis and treatment of any given lesion in the pelvis, it is always essential to remember that any one or more of various conditions may be responsible for the hæmorrhage.

A short time ago, when discussing with my house staff the number of cases of uterine hæmorrhage occurring in the Gynecological Department of the Johns Hopkins Hospital during the year, in which no definite cause for the bleeding could be ascertained, it was the general opinion that there had been only ten or twelve such during the twelve months. Thirty or forty years ago, the cause of uterine bleeding in many cases could not be definitely ascertained. Year after year our knowledge has been gradually increasing, until now, in a large clinic, there are not over a dozen cases in a year for which some satisfactory explanation for the bleeding cannot be given.

TREATMENT

I shall say nothing as to the handling of premature separation of the placenta, retained membranes or hydatidiform mole, you are as familiar with the proper method of treatment as I am. When a hydatidiform mole has been removed, the patient should be carefully watched for months, and should bleeding be noted, the uterus should be curetted at once and chorio-epithelioma kept in mind.

When possible, tubal pregnancy should be

diagnosed and operated upon before rupture. When the patient is in shock and almost in *extremis*, one has a strong impulse to operate immediately, but if she can be tided over for a short time and transfused just before or at the beginning of operation, the chances are very much better. Transfusion works miracles in such cases. One point to be noted in the technique when the abdomen is full of blood is this. Just so soon as the tube has been clamped so that its bleeding has been checked, and prior to its removal, it is well to pack a large roll of gauze into each flank, and a large Mikulicz pad into the pelvis. By the time the operator has removed the tube these three pieces of gauze will have soaked up a large part of the free blood and much time will be saved.

Hyperplasia in young people calls for curettage every few months, if the bleeding is excessive. In patients at or near the menopause a dose of radium will bring on the menopause. In carcinoma of the cervix, when the growth is limited to the cervix, the uterus freely movable, and the patient a good risk, the uterus should be removed. On the other hand, if the patient is very anæmic, has renal or cardiac trouble, or if the growth has extended to the vaginal vault, then radium seems to offer the best chance of relief. In cases of carcinoma of the body of the uterus, we invariably do an abdominal hysterectomy. In such cases, we first close the cervix with two mattress sutures, in order that none of the contents of the uterine cavity may escape. The vagina is then tightly packed with gauze and the abdomen opened. As all of you know, hysterectomy for carcinoma of the body of the uterus usually gives excellent and permanent results.

Small and medium-sized fibroids yield readily to radium and x-ray, but one is not always sure of the diagnosis. Three cases that have recently come under my notice may be briefly referred to.

CASE 7

Mrs. J. A. H., aged 40. Her periods for the last few months had occurred every two weeks, and had lasted from seven to ten days. On pelvic examination, the body of the uterus seemed to be about the size of a two or three months' pregnancy. A diagnosis of "fibroids" was made. Operation at the Johns Hopkins Hospital was performed on February 1st, 1928. As soon as the abdomen was opened the omentum was found to be adherent to the abdominal wall over a considerable area. The adhesions were loosened. On the right side, a piece of omentum, 4 cm. square, was

left attached to the abdominal wall, and the parent omentum cut loose. The omentum was also adherent to the pelvic brim on the left side. In loosening it up, two or three loops of the bowel were found adherent in the region of the cæcum. These were loosened and the raw areas turned in. At least five or six loops of small bowel were adherent to one another, which were separated with little or no bleeding. On the right side was an ovarian cyst, at least 8 cm. in diameter, and attached to it was a small cork screw like hæmatosalpinx. The mass was adherent in the pelvis. The adhesions were gradually loosened, and then the sigmoid was found to be adherent to the posterior surface of the cervix. A supravaginal hysterectomy was performed and the left ovary saved.

On histological examination, in addition to the lesions already mentioned, an extensive adenomyoma of the uterus was found. In this case the patient had had a tubal pregnancy seven years before.

CASE 8

Mrs. A. J. B., aged 45, was seen on February 2, 1928. Recently the periods had been excessive, and there had been a dark irritating discharge. On pelvic examination, the body of the uterus was found to be somewhat enlarged, globular, and free from adhesions. Nothing was detected laterally. Operation at the Church Home and Infirmary was performed on February 4, 1928. When the abdomen was opened, the uterus was found to be twice as large as usual, and behind it was some turbid fluid. It was decided to do a supravaginal hysterectomy. As we began to cut across the cervix, a yellowish gray, sloughing, submucous myoma, nearly 4 cm. in diameter was found, projecting down into the cervical canal. This was removed intact, together with the fundus, and then enough of the remaining cervix was removed to take away the cup-like depression in which the submucous myoma had rested. Both ovaries were saved. Three cigarette drains were laid in the pelvis and brought out through the lower angle of the incision. The patient had a very stormy convalescence, but made a good recovery.

From the clinical history, there was not the slightest idea that a submucous, necrotic myoma existed.

CASE 9

On February 7, 1928, Mrs. M. E., aged 38, came to see me. Her periods had been regular until four months previously. She then missed one period, and had some pain in the right lower abdomen, there had been some irregular bleeding. Occupying the lower abdomen, more prominent on the right than on the left side, was a globular mass which felt like a fibroid. One physician who had examined the patient thought she had a tubal pregnancy. In this he was supported by the history. Nearly every one else who examined this patient came to the conclusion that she had a fibroid.

Operation was performed at the Church Home and Infirmary on February 14, 1928. With the patient asleep, a mass could be felt to the right of the uterus. It was impossible to tell just what it was. A median incision was made and we immediately came down on a dark bluish gray mass, 8 by 5 cm. This was adherent to the descending colon and to the epiploic appendages. It was also adherent to the bladder peritoneum and it lay just beneath the anterior abdominal wall. It was gradually loosened, brought out of the abdomen and found to be a tubal pregnancy which came from the right side. Both ovaries were saved. The left tube was removed because it was blocked. The appendix was considerably enlarged and tied up in adhesions.

In each of these three cases one or more surgeons had diagnosed uterine fibroids, in none of them would the results with radium or x-ray

20th, 1928 She showed the classical symptoms of Graves' disease with the exception that exophthalmos was not present. The disease was apparently of six months' standing. She was placed on vitiodum, three capsules a day, on January 21st. The varying dosage, and the results, are shown in Chart II. There was a rapid, marked fall in the basal metabolic rate, accompanied by marked clinical improvement, including a fall of pulse rate towards normal. Subsequently two capsules a day seemed to hold the basal metabolic rate to just above the normal figure. She was operated on by Dr. Waugh on February 18th, under nitrous oxide. The left and three quarters of the right thyroid gland were removed. She made an uninterrupted recovery, her basal metabolic rate on February 27th was plus 11 per cent, and she was discharged from hospital on March 3rd.

The pathological report on the thyroid states "Both lobes are of a diffuse fleshy goitre presenting the typical appearance of Graves' disease. The microscopic picture is that of Graves' disease in a quiet period. In places the acini are distended with darkly-staining colloid and lined by flattened cells with a few projecting spurs. In other places the structure is denser, the acini are small and lined by cubical epithelium with scanty thin colloid. Thick dense strands of fibrous tissue run throughout the specimen. There are a few lymph follicles."

CHART II

CASE 3

Mrs. S., aged 43, Anglo-Saxon, housewife. She was admitted to the Winnipeg General Hospital on January 24th. She showed the classical symptoms of Graves' disease, except exophthalmos, and her history indicated that the condition was only of five months' standing. She had been given Lugol's solution, 15 minims three times a day, since the previous November until a fortnight before admission to hospital, when vomiting commenced, on which account she discontinued the treatment, whereupon her symptoms increased in severity.

She was kept in bed at rest for several days, without other treatment. At the end of this period her basal metabolic rate had increased from plus 31 to plus 45 per cent, so that the beneficial effect of rest as a complication

in judging the effect of vitiodum treatment can be excluded in this case. She was then placed on three capsules of vitiodum per day, with immediate clinical improvement, and an accompanying fall in the basal metabolic rate. During February 17th to 19th, inclusive, the vitiodum was discontinued, and there was an immediate sharp rise in the basal metabolic rate. The general results are seen in Chart III. She was operated on by Dr. Waugh on February 28th. He resected the left thyroid lobe, a further operation to remove the right lobe being deemed desirable at a later date. On March 12th her basal rate was plus 23 per cent, her recovery was satisfactory, and she was discharged from hospital on March 16th.

The pathological report on the left thyroid lobe states "One large lobe of a diffuse fleshy goitre presenting the meaty appearance of Graves' disease. The microscopic picture is one of very active hyperplasia, with, in places, evidence of regression shown by the appearance of densely stained colloid and dilated acini. The cells lining these acini are still, however, columnar in type. There are numerous collections of lymphocytes and a few thick bands of fibrous tissue."

Told to report to hospital in a month's time, she did not return until late in June. During the intervening period she had been for some time on Lugol's solution,

CHART III

though this was stopped a fortnight prior to readmission. Her basal metabolic rate on June 25th was plus 53 per cent. She was placed on the iodized fatty acid capsules (three a day). On June 29th the rate was plus 56 and on July 3rd plus 49 per cent. She showed no clinical improvement during this period. Commencing on July 3rd the vitamin capsules (3 a day) were also given, so that she was then getting the complete "vitiodum." On July 6th the rate had only fallen to plus 46, but on the 10th it had dropped to plus 30 per cent, with definite clinical improvement. The body-weight of 109 at admission was unchanged on July 3rd. By the 11th she had gained two pounds.

The second thyroid operation was performed on July 13th, the right thyroid lobe being resected by Dr. M. R. MacCharles. Post operative recovery was normal.

The pathological report on this lobe states "A goitre of moderate size, very firm, and on section presenting a dense meaty appearance. The microscopic picture is one of Graves' disease with marked epithelial hyperplasia, and very little evidence of involution. Many small collections of lymphocytes and some well formed lymph follicles are present."

"The picture is, if anything, a little more active than that of the previous specimen."

CASE 4

S. P., aged 24, Anglo-Saxon, farm-labourer. He was admitted to the Winnipeg General Hospital on March 14th, 1928. During the previous August he had been admitted with typical Graves' disease, and one thyroid lobe was removed. One month prior to readmission the symptoms recurred. On readmission he exhibited all the classical symptoms, with marked exophthalmos. On March 17th the basal metabolic rate was plus 38 per cent. He was placed on three capsules per day of vitiodum on March 22nd, and this dosage was continued daily until May 21st (with the exception of April 3rd and 4th). Tonsillectomy was performed on April 3rd. On April 17th a definite sore throat was observed, and on April 20th Vincent's angina was confirmed. After being placed on vitiodum he showed the usual clinical improvement, the basal metabolic rate on March 30th was plus 12 and on April 9th plus 11 per cent. On April 17th the rate had risen to plus 27 per cent (possibly due to the onset of Vincent's angina), and on May 7th was still plus 25 per cent. On May 21st Dr. Waugh removed the isthmus and the remaining (large nodular) left lobe, except the superior pole. Recovery was uneventful. On June 1st the basal metabolic rate was plus 10 per cent, and the patient was discharged from hospital on June 11th.

The pathological report on the left thyroid lobe states "The gross specimen is that of a large nodular goitre. Microscopically, the picture is that of a completely resting thyroid. The acini, however, are of about normal size, though some are rather dilated, and all are filled with densely staining colloid. The epithelium is quite flattened. There is one collection of interacinar cells which appears to be epithelial in type, but there is no epithelial budding nor other signs of activity."

CASE 5

Mary B., aged 21, Anglo-Saxon, clerk. She was admitted to the Winnipeg General Hospital on March 31st with the classical symptoms of Graves' disease, except exophthalmos. The history suggested that the condition had existed for eighteen months.

She was initially placed on capsules of the vitamin-fraction (3 per day) for four days, but since she developed an acute pharyngitis and temperature, no conclusion could be drawn as to the effect of these. On April 7th three capsules of vitiodum were given, none on the 8th to 10th, inclusive, (the pharyngitis persisting), but the same dose was recommenced on the 11th and continued until her discharge from hospital on the 29th. Her basal metabolic rate was plus 44 per cent, on April 3rd, on April 16th it had fallen to plus 18, with corresponding improvement in clinical symptoms, and on April 24th it was plus 16 per cent. At discharge she was instructed to continue taking two capsules of vitiodum per day, and on May 2nd this dose was increased to three per day. On May 9th the basal metabolic rate was plus 17, on the 23rd plus 14 per cent. On June 4th and 5th no vitiodum was taken, her supply being exhausted. On June 6th her basal metabolic rate was plus 30 per cent. The dosage of vitiodum has been continued until the present time, and throughout this period she has continued to work as a clerk.

On June 13th her basal metabolic rate was plus 24, on June 27th plus 25, on July 17th plus 16 per cent. Her weight at admission to hospital was 141 lbs., by April 16th it had fallen to 131 lbs., then rose steadily to 150 lbs. (June 6th), and remained near this figure, being still 150 lbs. on July 17th.

CASE 6

M., aged 45, Scotch, watchman. He was admitted to the Winnipeg General Hospital on November 25th, 1927, with Graves' disease and auricular fibrillation. Although this case is more complicated than the others it shows distinctly the beneficial effect produced by vitiodum, and this effect, and the salient features of the case, can, perhaps, be most easily seen by reference to Table I.

TABLE I

Data Concerning Case 6

June 15		108	+11
June 22		105 5	+27

89 lbs) on July 12th it was still plus 55, and on July 18th it had fallen to plus 42 per cent, with some slight but nevertheless definite clinical improvement

RESULTS

Cases 2, 4, 5, 7, 8, 10 and 11 were treated with vitiodum (or with the combined fractions of vitiodum) with definite results in all cases, though the response in Case 7 was slight. These cases had not had Lugol's solution prior to the vitiodum.

The few preliminary doses of Lugol's solution given to Case 1 can be disregarded. In this case also the response to vitiodum was excellent, both clinically and as indicated by the basal metabolic rate.

Cases 3, 6 and 12, were given vitiodum after Lugol's solution, but with a sufficient interval between the two treatments. The first two showed a marked, and the third a slight response.

The initial treatment of Case 9 with vitiodum was of too short duration to permit a definite conclusion. Her later treatment with vitiodum immediately following a prolonged course of treatment with Lugol's solution gave no beneficial response.

The results chronicled for Case 3 show that in this case certainly, and in the others probably, the beneficial effect of rest in bed can be disregarded as a dominating factor.

DISCUSSION

The following tentative statements obviously require the support of further evidence.

Discontinuance of vitiodum treatment is followed by a rapid increase in the basal metabolic rate (Cases 1 and 3) which falls again when the vitiodum is again given (Case 1). On the other hand after a prolonged period of dosage the vitiodum may cease to produce an effect (Cases 1 and 4), in this respect resembling Lugol's solution, although after a period without it when it is again given it is again effective (Case 6), in this also resembling Lugol's solution. Whether in certain milder cases it may be possible to treat Graves' disease medically by prolonged administration of vitiodum is still uncertain, although Case 5 suggests that this may be possible. Again in this respect there is a possible parallelism with Lugol's solution.

In each of the cases successfully treated with vitiodum there was noticeable a distinct initial fall of pulse-rate towards normal, persisting from a week to ten days, but then followed by marked fluctuations.

In several of the cases post-operative treatment

included administration of vitiodum, but since in all these cases Lugol's solution was also at that time administered to some extent, no conclusions can be drawn as to the safety or desirability of replacing Lugol's solution entirely by vitiodum subsequent to operation.

We have in this series deliberately excluded cases of the so-called toxic adenoma, since there is still definite difference of opinion as to whether Lugol's solution is without effect on this condition when it is uncomplicated. The frequent occurrence of mixed types of goitre render analysis of the effects of Lugol's solution difficult in such cases. Our results, therefore, though emphasizing the parallelism of the effects of Lugol's solution and of vitiodum, in no way prove that the latter may be without effect on toxic adenomata. Actual test must be applied to settle this point.

None of these cases showed any gastro-intestinal disturbance during or following the administration of vitiodum. Since such disturbance but rarely results from the administration of Lugol's solution, our series is too few in number to permit a definite statement as to an advantage of vitiodum over Lugol's solution in this respect, though it does suggest the desirability of ascertaining the effect of immediate transference to vitiodum of those cases that react badly to Lugol's.

We are indebted to Dr William Boyd, Professor of Pathology at this University and Pathologist of the Winnipeg General Hospital for the pathological reports on the thyroid tissue removed at eight operations on seven of these patients. Since two of the seven (Cases 3 and 4) were complicated by previous administration of Lugol's solution, which may possibly have affected the histological appearance of the gland, Dr Boyd does not think that the series is yet sufficiently extended to justify a definite comparison between the action of vitiodum and of Lugol's solution on the histological picture, though the results at least suggest some degree of likeness.

There are two theories current as to the action of Lugol's solution on the thyroid of Graves-disease, one, that there is a direct action on the gland itself, the other, that there is an indirect action, through the bactericidal action of the iodine solution lessening the amounts of toxic compound (or compounds) absorbed from the alimentary canal, and so lessening the degree of toxic stimulation to the thyroid. It is undesirable to discuss these theories here, though our results may have some bearing on them. But it

is difficult to imagine how a mixture of vitamins A and D and an iodized fatty acid can bring about a result comparable with that produced by a strong active solution of iodine in potassium iodide, although our results show that such is the case. It should, at any rate, be possible to determine whether all the components are necessary to produce the beneficial results, and this we have attempted to ascertain by using the two fractions separately.

Cases 9 and 10 exhibited no definite clinical response and no definite lowering of the basal metabolic rate when given the vitamin fraction alone, though the first subsequently responded satisfactorily to Lugol's solution, and the second to vitiodum. Case 11 and Case 3 (second period of treatment) showed no response to the iodized fatty acid fraction, though subsequently both responded satisfactorily to vitiodum.

These tests in themselves are insufficient in number, but they do suggest the strong probability that both the vitamin fraction and the iodized fatty acid fraction are necessary for definite effect. It remains to be determined whether both A and D or but one of them is necessary, and whether the iodized secolic acid can be satisfactorily replaced by iodides and other types of iodine compounds. We hope to solve these questions in further work, and also to extend the work in the direction of ascertaining the cause of the effectiveness of this specific combination. It would appear that there is here an example of *positive* vitamin action worthy of careful study, to be contrasted with the *negative* actions usually associated with vitamins in the prevention of certain pathological conditions, but which, of course, do not truly represent their normal physiological functions.

CONCLUSIONS

We draw the following conclusions from this series of cases

1 Vitiodum, a combination of vitamins A and D and an iodo-fatty acid, is as effective as Lugol's solution when administered in Graves' disease, its beneficial action, and the limits of its beneficial action, closely resembling those of Lugol's solution.

2 Vitiodum has not, in our experience, produced any gastro-intestinal disturbances during or following its administration.

3 It is probable that neither the vitamins nor the iodo-fatty acid alone are effective.

4 It is very desirable that further work be undertaken, not only to have records of a much larger number of cases accurately checked during vitiodum administration, but to investigate as widely as possible the relation between the vitamins concerned and thyroid and iodine metabolism.

We wish to thank the surgeons already named and also Drs Charles Hunter, J R Davidson, C R Gilmour, F A Young, H M Murdoff and H D Kitchen, of the attending staff of Medicine of the Winnipeg General Hospital, for permitting us facilities for the work now reported, and for their co-operation throughout the course of the work.

Our thanks are also due to Messrs Ayerst, McKenna and Harrison for the supplies of vitiodum and its fractions used in the investigation.

Van Helmont (1577-1644) prophetically expressed the idea of immunity and the cure of disease by immune sera. His words are "For he who has once recovered from that disease hath not only obtained a pure balsamical blood, whereby for the future he is rendered free from any recidivation of the same evil, but also infallibly cures the same affection in his neighbour and by the mysterious power of Magnetism transplants that balsam and conserving quality into the blood of another."

During the year 1927 the death rate from automobile accidents per 100,000 persons exposed was 17.9 in the United States, in Canada it was 10.9. While automobile fatalities in Canada are only rather more than half the proportion in the United States they have been increasing more rapidly of late years.

The figures for the various provinces during 1927 are as follows: Nova Scotia, 8.4, New Brunswick, 19.1, Quebec, 9.6, Ontario, 13.7, Manitoba, 0, Saskatchewan, 0, Alberta, 8.7, British Columbia, 11.1.

THE VALUE OF TRYPARSAMIDE AS A PROVOCATIVE AGENT IN THE DIAGNOSIS OF NEUROSYPHILIS*

By E C MENZIES, M.D.,

*Assistant Medical Superintendent, Verdun Protestant Hospital,
Verdun, Que*

GENNERICH, working with blood, first suggested¹ the use of salvarsan as a provocative agent in 1910. He used small doses of 0.3 and 0.4 grm., doing the blood Wassermann test daily for the succeeding week, as he believed that the reaction in the blood might occur within a few hours of giving the salvarsan, or be delayed for days. His results were such as to convince him that the procedure was of value and aided in the establishment of the diagnosis in many doubtful cases. O'Leary,² in 1920, working with a fairly large series of cases, came to the conclusion that the provocative dose added from 10 to 20 per cent of positive results. Craig,³ in a review of the subject in 1921, states that the use of salvarsan as a routine is fully justified, as the percentage of positive blood Wassermann tests is increased thereby.

The above facts refer to the blood Wassermann test alone and are so generally accepted that practically all syphilologists have for the last fifteen years recognized the value of the provocative dose of salvarsan as an aid in obtaining an accurate blood Wassermann reaction in doubtful cases.

The problem of the neurologist and the psychiatrist is however somewhat different from that of the syphilologist. The psychiatrist may be called in to see a patient suffering from a mental disorder and he may find by a routine blood Wassermann test that the patient has syphilis. He will then have the spinal fluid examined. If this is positive he usually feels justified in treating the case as one of neurosyphilis, even if the accompanying neurological signs and the mental picture are atypical of this disease. If, however, the spinal

fluid is negative after at least two examinations he will have difficulty in making a diagnosis.

In dealing with this precise type of case, namely, cases of mental derangement in which the blood test is positive, the spinal fluid negative, and the neurological and mental picture not very typical of neurosyphilis, we have for the past twenty-one months made use of tryparsamide as a provocative agent, in order to give us more accurate knowledge as to the spinal fluid Wassermann reaction. The purpose of this paper is to report briefly our findings.

Such cases are not extremely rare, as in a

CHART I

Case No 1—Chart of a very violent disoriented and homicidal patient aged 52 years. Admitted Nov 17 1926. The mental picture was not at all typical of general paresis of the insane but there were suspicious physical signs. After his sixth chill the patient suddenly became very excited and violent and died before a doctor could reach his bedside. An autopsy was refused.

CHART II

Case No 2—A woman 39 years old presenting a typical picture of tabes no mental involvement. She had been treated for years for lues and the tryparsamide was only given to note its effect on the Wassermann test.

* From a clinic at the Verdun Protestant Hospital, under the direction of Dr C. A. Porteous, Medical Superintendent, whose help and advice the writer gratefully acknowledges.

series of thirty-eight patients suffering from neurosyphilis we have had five in whom the spinal Wassermann was negative and one in whom it was doubtful. The other aspects, viz, cells, chemistry, and gold curves varied from negative and suspicious to positive findings.

APR 2/27	TRYPARSAMIDE GRAMS III MAR 26/27	++	++	230	+++
JUNE 23/27	MALARIA MAY 1/27			4	

Case No 3—Chart of a patient with no mental symptoms aged 54 years. When seen by us on March 26 1927 he gave a history of being treated intermittently for lues for ten years before and constantly for the past two years. He complained of intense supraorbital pain almost constant incontinence of urine and feces. He was confined to bed. The pupils were equal and reacted to light and accommodation. Right and left Babinsky sign present patellar reflexes very markedly increased marked ankle clonus the abdominal reflexes were absent. The patient gave a history of not being able to wash his face while standing for more than a year. Muscle-sense and touch were very much impaired over both lower extremities. The result of the puncture and blood done that day is shown in the above chart. It will be noted that the neurological picture was not typical of tabes and both it and the spinal serological picture could be explained by some cord lesion other than a luetic one. The result of the provocative dose is shown in the second section the third shows the serological picture after malaria. The physical improvement was just as striking. The man has worked ever since.

MAY 19/27	Blood	+++	+++		
		—	—	4	
JUNE 7/27	TRYPARSAMIDE GRAMS III MAY 31/27	+++	+++	17	+++

Case No 4—A woman aged 50 admitted after four weeks in a local hospital. She was reported by them to be negative neurologically and her serological condition as sent with the patient is shown in the upper section. Mentally the woman exhibited a picture of confusion and depression but nothing which would indicate neurosyphilis. We also found her negative neurologically. Our first serological finding is shown in the second section and after tryparsamide in the third. The patient failed so rapidly with us that malaria was not indicated and she died of a three-day intercurrent bronchopneumonia six weeks after admission.

The blood in every case was positive. Hoping to prove or disprove cerebrospinal lues a provocative dose of tryparsamide was given in each of these six cases and we present the serological sheets below.

CHART V

		ALC	CHLOS		
MAR 9/28	Blood	+++	+++		
		—	+	7	+
MAR 19/28	TRYPARSAMIDE GRAMS III MARCH 12/28	+	+	17	+

Case No 5—A man 13 years old presented a mild hallucinatory psychosis of a persecutory type. Physical signs were fairly typical and the spinal Wassermann test is shown to be doubtful on the first puncture. In this case we did not get a very striking reaction from tryparsamide but the physical signs were so marked that malaria was given. He apparently became sane during its course but unfortunately was killed in a street car accident ten days after discharge. So we shall never know just how complete his mental recovery was.

CHART VI

DATE	GOLD CURVE	CSF WASS		CELLS	CHEM
		ALC	CHLOS		
APR 12/28	Blood				
		—	—	32	+
APR 24/28	TRYPARSAMIDE GRAMS III APR 16/28			16	+
JULY 2/28	MALARIA IN MAY AND JUNE			7	

Case No 6—In this case we did not get a positive Wassermann test as a result of tryparsamide. The curve however became positive instead of doubtful. It is also to be noted that the curves of Cases 1, 3 and 4 were also slightly increased. The patient was thirty-six years old a typical tabetic with intense gastric crises and no mental symptoms. The serological finding after malaria is shown. Patient reports that he has gained in weight and is working steadily with no crises.

It will be seen that in five of these we obtained a positive Wassermann reaction following the use of the provocative dose of tryparsamide. In the sixth case we did not, but the curve was strongly increased. It will also be noted that in all these cases, with the exception of the first, the subsequent course of the disease or the concomitant mental and physical findings placed the diagnosis of neurosyphilis practically beyond dispute.

CONTROL CASES

When the idea of using tryparsamide as a provocative agent first occurred to us, we used as controls five cases of dementia præcox, who had been inmates of this institution for periods varying from one to twenty years. These patients all had positive bloods in spite of active treatment with novarsenobenzol and mercury. None of these præcox controls had ever shown physical or mental signs of neurological involvement and their spinal fluids had always remained negative for syphilis. In using them as controls the spinal fluid was first taken and again found to be negative in all reactions. The tryparsamide was given and a week later the spinal serological was again done. The result in every case and in every respect of each test was negative.

During these twenty-one months we have had nineteen patients admitted to us whose blood was found to be positive, but on examination the spinal fluid was negative. In some of these cases the mental and physical picture while not typical of cerebrospinal lues yet had symptoms such as to lead us to believe that neurosyphilis might possibly be the cause of their mental trouble. A routine provocative dose of tryparsamide and a repetition of the spinal tests still showed them to be negative, and up to date the subsequent picture presented by these patients has shown no indication of lues being the cause of their psychosis. In other words, the negative value of this procedure would so far appear to be of equal or greater clinical application than the positive. We are so convinced of this that we now make use of tryparsamide as a provocative agent in every mental patient who comes to us with a positive blood, but a negative spinal fluid. There were also seven patients with a negative blood and spinal fluid whose mental state, and in some cases whose physical condition led us to suspect that possibly lues might still be the cause of their trouble. We applied this procedure in these cases and got no reaction. On the strength of the negative result we excluded lues and so far our confidence in the value of our routine tryparsamide provocative in this type of case has been justified. The subsequent course of every patient of this type has proved that he did not have lues. We do not overlook, however,

that there is still time for some of the more recent cases to develop neurosyphilis.

A reference to the charts will show that the Wassermann reaction is the principal aspect of the spinal serology to be affected. The results on the gold curve, chemistry, and cells are neither uniform nor striking. We have at present a female patient, forty-four years of age, whose mental and neurological picture, while containing one or two features indicative of cerebrospinal syphilis, yet, on the whole was atypical of this disease. Her blood was four plus. The spinal fluid was also four plus, but there was absolutely no deviation from the normal in the gold curve, cells, or chemistry. We pursued our provocative routine with this case. The spinal fluid Wassermann was again four plus, but the gold curve, cells, and chemistry were utterly unaffected.

In this connection we have further to observe that those patients whose spinal Wassermann are ultimately proved to be positive had suspicious findings in either the gold curve, the cells, or the chemical tests. The cases which remained negative in spite of the provocative dose of tryparsamide showed as a rule much less deviation from the normal in these particulars. It further emphasizes the importance of studying as many aspects of the spinal serological examination as possible.

RATIONALE AND TECHNIQUE

Our experience with tryparsamide goes back to May, 1923, when we first began to use it. We have since then given it either with or without malaria to over one hundred and fifty patients. In many of these cases particularly during 1923 and 1924, before we were using malaria in conjunction with it, we frequently noticed an initial exacerbation or the clinical symptoms of the disease after the first or second doses of tryparsamide. Briefly, these were occipital headaches, pain in the back or the neck which extended down the spine, increase of tabetic pains, or a lighting up of these pains where none had been complained of before. It is also generally accepted that tryparsamide does gain entrance to the nervous system; it is, however, a weak arsenical and slow in its effect. The above considerations led us to believe that tryparsamide might be of value as a diagnostic agent if used in a pro-

vocative manner. It also led us to give a maximum dose of 3 grm intravenously and wait a week because of its retarded action before taking the spinal fluid, and that is the technique which we have followed in every case. We were tempted to make a spinal serological examination more often, but the majority of these cases chanced to be private patients and economic considerations had to be taken into account. Also we did not care to submit our patients to more lumbar punctures than were necessary.

The serological work has in all cases been done by Miss Fish, of the Medical Arts Building, Montreal, to whom we acknowledge our indebtedness.

It will occur to every reader that we have only a series of six to report, but it must be remembered that this type of case is not very common and that so far the procedure has been of value in every case. We are quite ready to admit, however, that even six swallows do not make a summer and our next six cases may show the above routine to be less effective.

Our chief reason for publishing this series, small though it be, is that from it tryparsamide, used as a provocative agent in obscure neurosyphilitic cases, seems useful, this also is borne out by the subsequent clinical course in the series. We hope other observers with larger clinics will use it, and assist in adding or re-

jecting the use of this drug in this particular manner, according to their findings in, we hope, much larger numbers of cases.

SUMMARY

1 A moderate number of cases of neurosyphilis, while showing a positive blood Wassermann reaction, will exhibit a negative cerebrospinal Wassermann and atypical physical and mental findings. We have had six such cases in a series of thirty-eight.

2 A provocative dose of tryparsamide given to these patients rendered the cerebrospinal fluid Wassermann positive in five cases and in one the gold curve also.

3 We have had other cases in which the picture presented by the blood and spinal fluid Wassermann was similar to these six. In some the mental and physical symptoms were such as to lead us to suspect neurosyphilis. A provocative dose of tryparsamide given to these cases showed no effect on the spinal fluid and the subsequent history of these patients showed that syphilis had not invaded their nervous system.

4 Cases of cerebrospinal luës with negative spinal fluid Wassermann tests usually show suspicious findings in the cells, gold curve, or chemical reactions.

Fissures of Nose—Richard L. Sutton describes lesions which occur at the anterior angle of the opening of the nose, and, while scarcely perceptible to the eye of the examiner, are very persistent, and give rise to considerable pain and discomfort. Not infrequently there is a secondary streptococcal involvement, which may cause slight fever and some intermittent redness of the tip of the organ. Dryness of the nasal mucosa and rosacea probably are provocative factors, but why the condition is almost wholly limited, at least in his experience, to middle-aged women, he does not know. The most effective agent is a needle-pointed electric cautery. With this modern "micro-brenner" the raw surface, previously put on the stretch by means of a nasal speculum, is carefully "ironed" out. Afterward, a dressing of ointment of yellow mercuric oxide (2 per cent) is applied. As a rule, relief is prompt and permanent.—*J Am M Ass*, 1928, xci, 567.

I think that if we were to search for one short phrase to characterize the difference between the newer physics and that of past times, I should choose the following: *The world is not composed of "things"*. To the metaphysician this is no new idea, but in the past the metaphysician could not point to the technique of science as being on his side, and he was therefore unable to combat the popular metaphysics which survived contentedly alongside of his speculations. Nowadays, physicists, the most hard-headed of mankind, the people associated more than any others with the intellectual and mechanical triumphs that distinguish our epoch, have embodied in their technique this insubstantiality which some of the metaphysicians have so long urged in vain. "We are such stuff as dreams are made on" was once a piece of poetic imagination, now it is among the presuppositions of physics.—Bertrand Russell, *Saturday Review of Literature*.

THE COMPLEMENT FIXATION TEST IN SCARLET FEVER AND ITS IMPORTANCE IN CARRIERS*

By F. GREEN, M.Sc., M.D.,

Montreal

FOR a long time the etiology of scarlet fever has been the subject of discussion and researches among various schools. Although Heubner¹⁴ and his followers are of the opinion that the streptococcus plays only a secondary part in the infection, yet the consistent bacteriological findings of Raskin,²³ Ranke,²² Baginsky and Sommerfeld,¹ Rumpel,²⁴ and Jochmann,¹⁶ who was able to isolate the *S. hæmolyticus* directly from the blood of scarlet fever patients on an average of 15 per cent of the cases and in 70 per cent of post-mortem examinations, have thrown considerable light on the subject.

The isolation by Dochez and Bliss⁷ of a certain strain of *S. hæmolyticus* from the throat of patients with scarlet fever in 100 per cent of case, the local reaction with a consecutive immunity against the disease obtained by injection of filtrates prepared with a specific *S. hæmolyticus* by the Dicks⁸, the blanching phenomenon in scarlet fever obtained by Schultz and Charlton²⁶ by injecting patients with the serum of convalescents from the disease, and the particular behaviour of the blood of scarlet fever patients in regard to the opsonic index of a certain strain of streptococcus as found by Tunnicliff²⁰, seem sufficient evidence, as Cushing⁵ says, that a certain specific strain of *S. hæmolyticus* must be considered as the etiological factor of scarlet fever. Although, of late, some authors, as Mandelbaum,²⁰ seem to have isolated a scarlet fever bacillus, yet the further study of classification of a particular strain of *S. hæmolyticus* by means of the precipitin reaction with absorbed serum (Lancefield¹⁵), and the studies of Szirmai,²⁷ Gerbas,¹² Blake³ and many others, seem still further to substantiate the theory of a specific *S. hæmolyticus* infection.

That on the other hand the scarlet fever

complex is not an anaphylactic production, as claimed by Szontagh,²³ Fanconi⁹ and Meyer,²¹ in the sense that the human organism, sensitized by a repeated simple streptococcal infection, would react anaphylactically to a new streptococcal invasion and would produce the scarlet fever symptomatology, seems to be an unfounded conclusion. According to Deicher, scarlet fever is not an anaphylactic shock, but a new infection altogether, and that this is so is proved by the fact that scarlet fever is cured by specific anti-streptococcal serum, which would not be possible in the case of anaphylaxis. And, moreover, the fact that children can build antibodies against the streptococci as well as adults does not explain why the former should be more susceptible to scarlet fever than the latter. Furthermore, according to epidemiological researches, susceptibility to scarlet fever diminishes as age increases, which, according to the anaphylactic theory, seems in reality to be just the opposite.

As Deicher⁶ says "In America, England, Hungary, France, Russia, Germany and Austria they are of the opinion that the *streptococcus hæmolyticus scarlatinae* must be taken as the causative agent of scarlet fever. We believe that the well known general success of the therapy of scarlet fever with artificial immune sera—prepared exclusively from streptococci or their toxins—represents a further striking evidence for the streptococcal etiology of scarlet fever."

The difficulties encountered by researchers in trying to fix the responsibility of this infection on one particular agent, through the fields of bacteriology and immunology, did not deter them from attempting to solve this problem by the complement fixation test.

The first authors to study scarlet fever by this test were Besredka and Dopter,² Fournier and Mallen,¹⁰ and Schleissner.²⁵ The first two authors used antigens prepared from streptococci cultured directly from the throat of

* From the Laboratory of the Shriners' Hospital for Crippled Children, Montreal Unit.

This research was undertaken at the suggestion of Dr. A. Mackenzie Forbes, Chief Surgeon, after an epidemic of scarlet fever had retarded the work of this hospital during the winter of 1923.

scarlet fever patients and from the heart blood obtained from post-mortem cases. In seven cases of scarlet fever, convalescent between the 7th and 33rd day, they obtained no fixation of the complement. These negative results convinced the authors that the streptococci were to be regarded only as secondary invaders in the disease.

Foix and Mallem used an antigen made up of nine strains of streptococci obtained from cases of scarlatinal angina. They tried the complement fixation in cases of scarlet fever in various stages of the disease, and also in cases of erysipelas and puerperal sepsis. They examined 12 scarlet fever patients between the 4th and 30th day of infection and concluded that the serum of scarlet fever patients contains antibodies against the streptococci, antibodies which were put in evidence by the complement fixation 10 times out of 12. These antibodies were quickly formed and could already be detected after the 4th day of the disease, they lasted a long time and could still be found on the 38th day and possibly even later than this. The reaction failed in other streptococcal infections.

Schleissner,²³ in 1909, having prepared an antigen from streptococci isolated from the blood of patients with scarlet fever, had occasion to study this reaction in a large number of cases. Of 13 cases between the 1st and 6th day, 6 gave a positive fixation, of 25 cases between the 7th and 35th day, 19 were positive, of 4 cases after the 35th day, only one gave a positive reaction. Numerous control sera used were always negative. In 32 cases, in which this author employed antigens prepared from streptococci isolated from other acute infections, like erysipelas, the results were invariably negative, although he obtained a weak fixation with the sera of patients of puerperal sepsis and of panophthalmia. This author is of the opinion that the constant presence of streptococcal antibodies in scarlet fever patients, as revealed by this biological reaction, speaks for the reliability of the test. He also states that these antibodies are present without exception between the 2nd and 5th weeks of the disease, are scarce or nil in the 1st week, and disappear from the blood by the end of the 6th week. These antibodies seem to be at their height in the blood of the patients on

the 10th day of the disease. He, however, does not think that the complement fixation is a sure method of differentiating the various species of streptococci.

Schleissner's results were soon confirmed by Laverato²⁴ who, having studied 18 cases with various antigens of *S. pyogenes*, *Staph. aureus*, *Staph. albus*, diplococci of Frankel, *B. typhosus*, *B. influenza*, *B. coli* and *M. tetragenus*, obtained in all cases a fixation only with the streptococcus antigen, the results being negative with all the others.

Cantacuzene and Bonciu²⁵ only recently studied the relation between the *S. haemolyticus* and scarlet fever convalescents by means of this reaction. As antigens, they used the toxin of Dick, a suspension of *S. haemolyticus* isolated from scarlet fever patients, one prepared from the *S. erysipelatis*, and also an indifferent antigen that of Bordet and Ruelens as employed in lues. These authors studied 150 cases of scarlet fever in the various stages of the disease. Of 32 cases in the first 15 days of illness, 4 sera fixed the complement with the Dick toxin as antigen, of these 4 sera, 2 showed also a retarded haemolysis with the suspension of the *S. haemolyticus* cultured from scarlet fever patients and also with the Bordet and Ruelens' antigen. Of 118 bloods taken between the 30th and 40th day of the disease, only 19 were positive with the Dick toxin. Of the 19 sera, 3 gave also a very strong reaction with the suspension of *S. haemolyticus* and with the Bordet and Ruelens' antigen. Of these 19 patients, 12 had received antistreptococcal serum during the disease. The authors concluded that in 16 per cent of scarlet fever cases one may get a positive complement fixation by using the Dick toxin as antigen. They regard the complement fixation reaction as not specific, having always obtained negative results with the immune sera of horses vaccinated with the Dick toxin.

It is remarkable that the above-mentioned investigators, although all using antigens prepared from cultures of streptococci isolated from the blood stream or from the throat of scarlet fever patients, have obtained such varying results, Laverato, 100 per cent, Foix and Mallem, 83.4 per cent, Schleissner, 61.88 per cent, Cantacuzene and Bonciu, 16 per cent.

INVESTIGATIONS IN THE SHRINERS' HOSPITAL, MONTREAL

In this hospital, some time after the abatement of an epidemic which occurred during the past year, six fresh cases of scarlet fever developed among both children and nurses, with exceptionally long intervals between them, and when for a long period there had been no fresh admissions to the wards. Strict orders had been enforced to prevent contact with the outside and especially with visitors to the patients, and yet cases of scarlet fever continued to make their appearance. The efforts in this direction having proved futile, at the suggestion of Dr. Forbes I tried to ascertain the source of infection by performing the complement fixation test on a selected number of patients and I was particularly requested to examine the blood of a certain woman attendant who had suffered from time to time with a severe sore throat (but who had not had scarlet fever). To this effect, I undertook this research, first, to see if the complement fixation test were at all practical and, if so, to estimate its value in detecting carriers.

I worked with several antigens

1 One prepared from strains of *S. hæmolyticus* (Dick) isolated from scarlet fever (American Type Culture Collection, Chicago)

2 Another prepared from *S. hæmolyticus* (Loewe)

3 *S. pyogenes* isolated from cases of puerperal sepsis, *S. hæmolyticus* isolated from cases of septicæmia, and the polyvalent streptococcus vaccine Sherman No. 42

4 An antigen represented by the scarlet fever streptococcus antitoxin of Parke, Davis and Co. (Detroit)

5 The antistreptococcus serum (Lederle)

Strange to note is the fact that these two last mentioned antitoxins (Nos. 4 and 5) behaved in a manner similar to true antigens. The explanation of this cannot for the present be accounted for.

After the titration of each antigen, one half of its anticomplementary dose was used. The antigens which proved to be the best and most suitable were the first two mentioned. The amount of serum of the patient used was 0.2 c.c. All sera examined were obtained from patients not treated with specific antiserum.

The results obtained were the following

Of 18 cases of scarlet fever between the 1st and 7th day, 4 were positive

Of 14 cases between the 7th and 14th day, all were positive

Of 2 cases between the 21st and 28th day, 1 was positive

Of 3 cases between the 28th and 35th day, 1 was positive

The serum of the suspected carrier was strongly positive

With 150 sera of various diseases examined as controls and using the same antigens, the results were always negative

So that of 41 cases of scarlet fever examined, a total of 23 positive reactions were obtained, or an average of 57.5 per cent, in all stages of the disease

When it was found that the serum of the suspected carrier referred to above gave a strong complement fixation with all the antigens, while all others of this hospital gave uniformly negative results, the hospital authorities decided to keep the suspected person away from the establishment. Whether this particular case was the cause of these scarlet fever cases may be judged by the fact that since the dismissal of this attendant no more cases of scarlet fever have been reported.

From a glance at the results obtained with the complement fixation test by the various workers, excepting the conflicting ones of Besiedka and Dopfer (10 per cent) and those of Livierato (100 per cent) one may well note a few important points. The complement fixation test, using a polyvalent antigen of *S. hæmolyticus*, has a tendency to be negative in the first week of the disease. This seems also to agree with the findings of Joehmann, (as I had occasion to see personally when working with him), who never succeeded in isolating the streptococcus from the circulating blood of these patients in the 1st or 2nd day of the disease even in the so-called fulminating cases. Apparently not sufficient antibodies are yet formed at that stage. The test gives the highest percentage of positive results between the 2nd and 5th week of the disease. The test has a marked tendency to become negative again after the 6th week. These results were obtained, as previously stated, in cases not treated with specific serum therapy.

A positive complement fixation in patients treated with specific serum is naturally difficult to interpret and the time at which a complete disappearance of these artificially produced antibodies from the circulation will take place is, as this test shows also in other diseases, like gonorrhœa, very difficult to fix. In my opinion, this is of much less importance than in other diseases, the focus of infection—throat and tonsils—being more accessible to treatment and to bacteriological examination. But as the streptococcal serum is as a rule given in the first or second week of the disease when the most severe complications are more likely to take place and as the naturally formed antibodies are mostly eliminated by the sixth week, also the artificially produced ones would as a rule be more or less eliminated by that time. In my opinion also, patients convalescent from scarlet fever with a negative bacteriological throat examination and a negative complement fixation could be safely discharged, while those with a negative bacteriological examination but a positive complement fixation should be regarded with suspicion and kept isolated for a longer period.

PERIOD OF INFECTIVITY

The time at which convalescence of scarlet fever patients begins, according to the majority of authors, is with the apyretic state of the patient and it is also at this time or later (3rd or 4th week of convalescence) that desquamation begins. The patient, in non-complicated cases, is discharged as a rule at the end of the 6th week from the beginning of convalescence. With regard to this routine, of late, the opinions of some clinics and laboratories seem to differ.

Helbig¹⁰ maintains that above all things the prophylaxis against a new infection of the mucosæ among the convalescents of scarlet fever in the hospital is very important for a continuation of isolation. The demand of other authors— isolation longer than 6 weeks—he maintains is not applicable. How long the non-complicated cases of scarlet fever can be infectious is not yet ascertained, according to him. "In those cases with septic complications, the necessity of a prolonged isolation is well known."

Friedmann and Decher¹¹ say "As source of transmission of scarlet fever, practically only the streptococci present in the throat of patients and in the septic complications of

scarlet fever have to be taken into consideration, skin desquamations and urine do not contain streptococci and are consequently not infectious. But the scarlet fever streptococci are found in large quantities all over the surroundings of the patients. In 100 per cent of the patients kept in hospital after 6 weeks and sent home as convalescent, scarlet fever streptococci were found on the tonsils. The construction of convalescent stations is for this purpose an indispensable necessity. The hemolytic streptococci of scarlet fever forming the toxin are capable of a metamorphosis into atoxic green streptococci which can again transform themselves into typical scarlet fever streptococci."

The bacteriological findings seem to be unanimous in condemning this arbitrary 6 weeks' convalescence, and moreover there seems to be evidence in the literature that contact with such convalescents has given rise to fresh cases of scarlet fever, as mentioned by Kirkbride and Wheeler,¹² who conclude "Hemolytic streptococci producing potent toxins have been isolated from patients after recovery from typical scarlet fever, from 30 days to 6 months after the onset of the disease. Evidence has been obtained that occasionally typical cases of scarlet fever may occur as a result of contact with such convalescent carriers or with normal carriers." And Decher says "We emphasize the claim that, as a principle on discharging convalescents from fever, the principal point should not be a schematic 6 weeks' isolation, but 3 consecutive examinations from that time showing that the mouth of the patient is free from *S. hemolyticus*."

This contagious disease which, in Montreal, occupies third place, with measles first and tuberculosis second, according to the *Health Bulletin*,¹³ averages 150 or more cases per month. In all probability, this number could be greatly reduced if the health authorities, besides imposing a compulsory and repeated bacteriological examination of the throat after the 6 weeks' convalescence, would exact also the same routine examination on all contacts together with a complement fixation test in those cases where there was a suspicion of possible carriers.

CONCLUSIONS

The complement fixation test for scarlet fever,

in the limited number of cases examined shows that

1 A negative result is the rule in the 1st week of the disease and also after the 6th week of convalescence

2 A positive fixation is obtained always between the 2nd and 5th week of the disease

3 A positive fixation obtained after a 6 weeks' convalescence and in apparently healthy persons but with a throat infection bespeaks an active infection warranting the isolation of such persons as carriers

4. The uniform results obtained with antigens prepared from the *S. hæmolyticus* seem to further confirm the theory of its being the etiological causative agent of scarlet fever

I wish to extend my thanks to Doctors A. Mackenzie Forbes, L. J. Rhea, H. B. Cushing and A. H. Mac Cordick of the Shriners' and Alexandra Hospitals for the valuable assistance which they have afforded me in the way of facilities for carrying out this research

STATISTICS AND THE MORTALITY RATE FROM DIABETES

By I. M. RABINOWITCH, M.D.,

Montreal

IN the introductory chapter of "Medical Biometry and Statistics," Professor Raymond Pearl¹ repeats the following quotation of Dr Lawrason Brown

"None of you will contradict me when I say that statistics are very dry, but some of you may dispute with me when I say that only by statistics does the world, lay or medical, advance. Consider what knowledge is and you will see how inseparable it is from statistics. Medicine is no exact science, and diagnosis rests largely upon the law of probability which, in turn, is statistical. All scientific experiments are statistical arguments in favour of, or in opposition to, certain inductions or deductions. Further, statistics lend the authority that is necessary for their acceptance.

"The trouble in medicine does not lie with the statistical method, but with the medical men who do not know how to use it. I regret to state that I belong to this class, and have felt keenly that in medical school I did not have an opportunity to attend a course on medical statistics. The day will come, gentlemen, when such courses will be given, when the law of probability will help in diagnosis when the coefficient of correlation now explained by most authorities in such terms that in a few minutes my idea of my relation to my surroundings has become totally insufficient—when, I say, all these things will be understood by the medical graduate. At that time medical men will cease to do such foolish things with statistics as to try to add cabbages and cows

or, what is nearly as bad, to try to solve problems in heredity by finding how many parents had the disease from which the offspring suffers, without due respect to many other very important and possibly contradictory details. What would you think of a bookkeeper who, after years of personal experience, would gather up the bills in the cash drawer and go to the bank with the statement that his personal experience led him to believe that the roll of bills amounts to \$1,000? The receiving teller would quickly apply the statistical method and few would venture to side with the bookkeeper, no matter how large his experience had been."

I have been prompted to extract this quotation on reading an article recently contributed by Dr Henry J. John on "A statistical study of 2,000 diabetics."² In this paper Dr. John records mortalities amongst his 2,000 patients which, from the point of view of the diabetic, are, to say the least, disturbing. In view of these findings I have considered it advisable to make a careful analysis of the data supplied. Comments upon the results of this analysis form the subject matter of this communication.

A brief reference may first be made to a recent communication in this *Journal*³ in which I demonstrated the effects of modern treatment upon the mortality rate from diabetes mellitus. It was shown that in a large population of properly treated diabetics, the mortality rate now approximates the normal population death rate. The demonstration was statistical. The significance of mortality rates was also discussed. The possible fallacies of the use of "crude" death rates and "personal experience," and the importance of expressing mortality rates as ratios of "actual to expected" deaths was shown.

Turning now to Dr. John's paper, we find the statement made (p. 217) that the study covers the period from March, 1921, to November, 1927, and later on (p. 244) it is stated that of the 2,000 patients observed during that time (seven years), 131 died. That is, there was a crude mortality rate of 6.55 per cent. Since this represented a crude rate, it was expected that somewhere in the body of the paper consideration would be given to the factors essential for the proper interpretation of this rate, namely, (a) a division of the cases into

groups of those observed in the pre-insulin days and those since the discovery of insulin, and, (b) calculations of ratios of actual to expected deaths. It is general knowledge that the results of treatment in the days prior to the use of insulin differ markedly from those of the present day. No such division of cases was made, however, neither was an attempt made to correlate the actual deaths with the number of those expected. As a matter of fact, not only was the latter operation not performed, but "EXPECTED" deaths seemed to be of little significance to the author. This may be concluded from the following:

On page 244, it is stated that "while the total mortality is 6.55 per cent, if the deaths in the seventh, eighth and ninth decades were excluded, *because of the natural incidence of death in these periods,*" (the italics are mine) "the mortality incidence would drop to 4.4 per cent."

Such a procedure can only be the result of disregarding recognized statistical methods. The assumption here is that the natural incidence of death has little significance, and also that there is no natural incidence of death at different periods of life. As a matter of fact, not only experience, but a glance at any of the existing "Life Tables" shows there is an expected death rate for every age. This, as is well known, should be taken into consideration in the interpretation of mortality rates. When this was done by the writer with Dr. John's data, the conclusions drawn were found to be just the reverse of those recorded. This will presently be shown by a reassessment and recalculation of the data given.

On page 218 (Table I) will be found Dr. John's classification of his cases, according to age and sex. I have taken the figures representing the total populations, according to the different decades, and calculated the expected number of deaths for each, with the following results:

	Popula tion*	Actual deaths†	Expected deaths	Actual Expected
Second	53	8	0.33337	24.2
Third	115	7	0.79235	8.8
Fourth	242	7	2.02554	3.4
Fifth	463	16	5.55600	2.8
Sixth	553	45	11.51899	3.9
Seventh	528	34	22.28688	1.5
Eighth	14	8	1.29738	6.1

* Taken from Table I, Dr. John's records, page 218

† Taken from Table XIII, Dr. John's records, page 245

Unfortunately, in calculating the above ratios of actual to expected deaths, the results are only approximate. This must necessarily be so, since Dr. John has grouped the population by decades. More exact values could have been obtained had all of the patients been classified according to their ages when first observed. For the same reason I have omitted calculations for the first decade. A glance at any "Life Table" will show the marked variation in the number of expected deaths of each age interval during this decade. Thus, (from Glover's Table II) —

Age	Deaths per 1000 living (1900 ex)
0-1	114.62
1-2	27.62
2-3	12.34
3-4	7.83
4-5	5.65
5-6	4.66
6-7	3.91
7-8	3.30
8-9	2.82
9-10	2.47

On the other hand, in the later decades, the variations in the death rates are gradual. As a matter of fact, if the death rate (factor q_x) corresponding to the middle age of each decade is made use of, though the results are by no means exact, they are sufficiently accurate for the present purpose.

Let us now compare the results of the above calculations with the statements made in Dr. John's paper.

(a) On page 244 the statement is made that "the seventh decade shows a high incidence of mortality, as does the fifth decade." As a matter of fact, the seventh and fifth decades show the lowest ratios.

(b) The statement is made on the same page that "the heaviest mortality is in the sixth decade." It will be observed that the highest ratio of actual to expected deaths is in the second decade and the ratio of the sixth decade is amongst the lowest.

(c) For the same reasons, the conclusion on page 247 that "the corrected mortality was 6.4 per cent" amongst the surgical group of cases is erroneous.

In a previous paper,⁴ Dr. John reported the results of a study of 1,000 cases. The investigation covered the period of March, 1921, to August, 1925. Since the second paper includes all cases, it was thought that some additional

information would be obtained if the data of both papers were reassorted. Thus, since the first 1,000 cases include all those to August, 1925, the second 1,000 patients must have been observed from August, 1925, to November, 1927. In other words, though the first group of cases were influenced by treatment of pre-insulin days, the second group belong to insulin days only. My attempt to make some such re-assortment failed, however, because the data supplied were insufficient, for although Dr. John records the deaths corresponding to the different decades in the second paper, which includes all of the 2,000 cases, no corresponding data are given in the first paper. The only available information in that paper is the total number of deaths amongst the 1,000 cases and the classification of patients, but not deaths, according to decades. Although it is, therefore, impossible to compare the ratios decade by decade, it is possible to approximately determine the ratios of actual to expected deaths of the two groups as a whole and compare them. This I have done, with the following results.

Since the number of deaths recorded amongst the first 1,000 diabetics was 62 (Table XVII, page 87, first paper) and, since the total number of deaths for the whole group was 131, there must have been 69 deaths amongst the second groups of patients. In Table I of the second paper are shown the populations of the two different series by decades. It is, therefore, possible to calculate the ratio of expected deaths for the two groups as a whole. From these calculations it may readily be observed that the ratio of actual to expected deaths amongst the first 1,000 cases was 2.6 and the ratio for the second 1,000 was 3.10. The conclusion to be drawn from these two figures, is as obvious as it is erroneous. The conclusion would be that in the Cleveland clinic, the mortality rate since insulin was greater than before insulin. I am certain Dr. John would not care to admit that. His clinic is modern and his results since insulin are as satisfactory as may be found in any other well established clinic. The death rate must, therefore, have been lower since insulin. This is suggested not only from various statements made by Dr. John, but also from the satisfactory results amongst his group of surgical cases, as shown in Table II of his second paper. The deduction, therefore, is that since

the results are more satisfactory and the mortality rates are lower, the mortalities given by Dr. John must be the result of defective methods of analysis and not the fault of treatment.

Among the conclusions is found the statement (page 247) that "the general belief among the laity that insulin once used must always be continued is shown to be fallacious." Here, again, an analysis of the data shows a faulty basis for this statement, for the following reasons:

No further proof, clinical or experimental, is necessary to show that all diabetics are not alike but that there are different types. For example, there is the juvenile diabetes, the acute diabetes of adults, the mild chronic progressive type whose tolerance is lowered by infection, the non-complicated chronic progressive type, the "gall bladder" diabetic, etc. In each of these groups, as is well known, the progress is different, the reaction to diet is different and the reaction to insulin treatment is different. Insulin dosages, as we know, are also influenced by other factors, such as exercise, etc. The effect of many of these factors in influencing insulin dosages were studied by the writer.⁵ Dr. John, according to his data, made no classification of his cases, nor did he determine whether insulin was at all necessary. Proof of this is found in the body of the paper, on page 222, where the statement is made "It is my practice to administer insulin to every patient when he first comes to the hospital." Such treatment, though it may shorten the period of stay of patients in hospital, as Dr. John suggests, can certainly not form the basis of the statistical conclusion which he recorded, since, with this practice, one may find hundreds of diabetics who, having been given insulin for short periods of time, are able to discontinue the use of it. Two questions which arise here are, (a) Was carbohydrate tolerance improved by the use of insulin?

(b) Was insulin actually required? That so many of Dr. John's patients discontinued the use of insulin after periods of two, three or more days' treatment, since the majority of periods represent days and not weeks or months (see Table II of first paper and Tables V, VI and VII of second paper), very strongly suggests that none was required to start with, though it may have been good practice in order to reduce hospital days.

These are a few of the observations which may be made apropos of the paper referred to. The conclusion is that no evidence is offered which tends to disturb the hopeful outlook of the diabetic. The mortalities recorded by Dr. John, which were disturbing before they were analyzed in detail, are, on examination, shown to be not real, but the result of his method of analysis.

The reason for publishing my observations is to call attention to the importance of statistical accuracy. Unfortunately, it is the rule, rather than the exception, that, in modern medical literature, one finds what purport to be statistical reports, but which, in reality, are nothing more than a mass of meaningless and therefore useless, data. In order to avoid unnecessary additions to the ever increasing literature of medicine, statistical reports should be regarded as justifiable only when they are exact and useful. The present state of affairs is still more deplorable, since such errors occur so frequently in the better type of journals, and are made by the better writers who, otherwise, are authorities in their respective subjects.

"When your dressings have been carefully applied, do not interfere with them for some days, keep the air out, for a wound left in contact with air suppurates. However, should pain and heat arise, open and wash out again, or even a poultice may be necessary, but do not pull your dressings about, nature works better left alone. Beware that your needles are clean, or they will

infect the wound. Do not allow the wound to bleed. For oozing use styptics, for jets of blood the cautery, but the disadvantage is that when the eschar falls off, bleeding may recur. Digital compression for an hour is useful, and occlusion for large vessels, or if the vessel can be isolated let it be drawn out, twisted and ligatured."—Henri de Mondeville (1260-1320)

ON THE OCCURRENCE OF BLOOD DYSCRASIAS FOLLOWING THE ADMINISTRATION OF NEOARSPHENAMINE*

By W. ROLAND KENNEDY, B.Sc., M.D.,

Montreal

WITHIN the last decade medical literature has contained from time to time contributions describing reactions with unusual blood-pictures following the use of arsenical preparations in the treatment of syphilis. Leredde¹ and Labbé and Langlois² were the first to report in 1919 the appearance of such blood dyscrasias. The rarity of these conditions and, at times, the severity of their course are the prime reasons for the publication of this case.

The patient, a negress, aged 26 years, was admitted into the Montreal General Hospital on April 2, 1927. Her complaints were those characteristic of cardiac decompensation. The final diagnosis was that of aortitis luetica with aortic insufficiency. Before her entrance to the hospital her family physician had had a serological examination made, the report from the blood Wassermann test was strongly positive (3 plus). Subsequently the patient was given two intravenous injections of neoarsphenamine, 0.45 gm. each, at weekly intervals, and one intramuscular injection of mercury salicylate, grain 1. The only other physical finding of interest on admission was that of a barely palpable spleen. The red blood cells were 4,800,000 per c.mm., the white blood cells 8,400 per c.mm., and the haemoglobin 72 per cent (Dare). The blood Wassermann was strongly positive (3 plus) on two occasions while in hospital. Under rest in bed and courses of digitalis compensation was soon established. Six intravenous injections of neoarsphenamine, 0.45 gm. each, were given at weekly intervals without untoward effect. In addition, potassium iodide, in daily doses of 40 to 60 grains, was given by the mouth. The patient was then discharged to the Out Patient Department of the hospital where antiluetic treatment was continued. From June 6th until October 11th, the patient received seven intravenous injections of neoarsphenamine in increasing dosage from 0.45 to 0.6 grains. Intramuscular injections of mercury salicylate were given on weeks that neoarsphenamine was not administered. It was noteworthy that after the last injection, a papular rash was observed on the lower extremities. On November 22nd the blood Wassermann was still strongly positive, but a rest from treatment was decided upon.

The patient was not under observation again until April 3, 1928, when she reported to the Out Patient Department with symptoms and signs of cardiac decompensation. A slight icteroid tinge to the conjunctivae was also found. The patient was readmitted to the ward on April 11th. The cardiac condition was essentially the same as on the previous admission. On this occasion both liver and spleen were readily palpable. A positive indirect van den Bergh test was also reported. On April 12th a catheter specimen revealed a specific

gravity of 1013 and some albumen (one plus), occasional pus and epithelial cells, but no red blood cells. The blood Wassermann was once more strongly positive. On April 13th the red blood cells numbered 4,800,000, white blood cells, 6,000, and the haemoglobin was 95 per cent (Hellge). On April 23rd the patient was given intravenously 0.3 gm. of neoarsphenamine. One hour afterwards profuse oozing from the gums and less severe epistaxis occurred and continued till the morning of April 25th. A mild haematuria also existed. The blood loss was estimated at about 1,000 c.c. On April 24th the bleeding time was 12 minutes (Duke's method). The coagulation time was 6 minutes (Lee and White's method). There was no retraction of the clot at the end of one hour. The platelet count was 60,000 per c.mm. The presence of purpuric lesions on the skin could not be determined on account of melanism. No petechiae were noted on the mucous membranes of the mouth. The hematologist, Dr. E. S. Mills, considered the hemorrhagic condition as a toxic purpura. Local applications of adrenalin, special dental plates to apply pressure to the gums, and 0.3 gm. of sodium thio sulphate intravenously were prescribed to control bleeding. No other symptoms were present. On May 16th, the red blood cell count was 3,000,000, white blood cells were 7,600, and the haemoglobin 57 per cent (Hellge).

On May 16th, twenty-two days after the last injection, 0.15 gm. of neoarsphenamine were given to the patient intravenously. Two hours later oozing from the gums and epistaxis reappeared. A catheter specimen of urine showed red blood cells. The stool was faintly positive for blood, but possibly this resulted from the swallowing of blood. The menstrual period was present at the time and thus was more profuse than usual. No retinal hemorrhages were discovered. Local applications to the gums and nose were employed in the form of a tannic and gallic acid mixture and adrenalin. That night 0.3 gm. of sodium thio sulphate were injected intravenously. The following morning the oozing had ceased. The red blood cell count was then 3,800,000, the white blood cells were 5,200, and the haemoglobin 63 per cent. The differential count showed 42 per cent polymorphonuclears of the neutrophilic type, 41 per cent small lymphocytes, 5 per cent large lymphocytes, 9 per cent monocytes, 1 per cent of eosinophils, basophiles and myelocytes respectively. The bleeding time was 10 minutes and the platelets numbered 145,000 per c.mm. The blood calcium was reported as 12.7 mgm. per 100 cc. of serum. On May 31st the blood findings were as follows: red blood cells 3,200,000, white blood cells, 7,100, haemoglobin 75 per cent, neutrophilic polymorphs 47 per cent, small lymphocytes 42 per cent, large lymphocytes and monocytes, 1 per cent, basket cells, 4 per cent, myelocytes 1 per cent, eosinophiles 2 per cent, platelets 370,000, bleeding time, 12 minutes.

SUMMARY

Summarizing, the above patient developed in the course of antiluetic treatment with neoarsphenamine a hemorrhagic diathesis with bleeding from the gums, epistaxis and hematuria. There was no untoward history of a similar character in either family or personal history. Of particular interest were the blood

* From the Clinic of Dr. C. P. Howard, Montreal General Hospital.

findings, a much reduced platelet count, a prolongation of the bleeding time and non retractility of the clot. With cessation of bleeding there was a rapid return to normal of the blood platelets and bleeding time. In short, there existed a toxic thrombopenic purpura or purpura hæmorrhagica.

DISCUSSION

The blood dyscrasias developing in cases of syphilis under treatment with arsenical preparations fall into three fairly distinct subdivisions: (a) purpura, (b) purpura with hæmorrhages, (c) aplastic anæmia with hæmorrhagic diathesis.

Purpura—This group is characterized by a purpuric eruption involving the skin and mucous membranes. The extent of the lesion may vary considerably. Bleeding from the mucous membranes does not occur. The frequent association of fever and a general symptomatic reaction are of note. Anwyl-Davies³ reported a case in a young woman supervening after ten injections of neoarsphenamine. The condition appeared twelve hours after the last injection and was accompanied by an acute general upset and a moderate febrile reaction. Moore and Foley¹¹ demonstrated in their cases a well-defined blood picture. There was a distinct leucopenia, with a relative and absolute decrease in polymorphonuclear cells, an increase, both relative and absolute, of cells of the mononuclear series. Small lymphocytes remained in normal proportions. Recovery is the rule but such disturbances are warning signals against further use of the arsenical preparation responsible.

Purpura with hæmorrhages—Distinctive of this subdivision is the appearance of hæmorrhages from the mucous membranes in addition to the purpuric manifestations of the skin and

mucous membranes. In typical cases there have been described oozing from the gums, epistaxis, rectal hæmorrhages, uterine hæmorrhages, hæmaturia and retinal hæmorrhages. This class is also separated from the previous group by a marked decrease in the blood platelets, a prolongation of the bleeding time, and non-retraction of the clot. This is a symptomatic thrombopenic purpura in contradistinction to the earlier group which is a non-thrombopenic purpura. The remaining blood picture is similar. Weil and Isch-Wall⁴ cite two fatal cases. In one, the patient had received two injections of neoarsphenamine (0.1 and 0.15 gm. respectively). The red blood cells numbered 3,000,000 per cmm and the patient died from a general intoxication.

Aplastic anæmia with hæmorrhagic diathesis—Distinguishing this variety is the occurrence of a severe primary, aplastic anæmia with purpuric and hæmorrhagic manifestations. This type is only differentiated with difficulty from a primary or Addisonian anæmia. In fact neoarsphenamine intoxication should be considered as a causative factor in a cryptogenic primary anæmia. The resulting course is often rapid, stormy and fatal. Blood smears reveal anisocytosis, poikilocytosis, basophilic degeneration and stippling. As in the preceding types leucopenia, agranulocytosis, relative lymphocytosis and increase in the monocytes are characteristic. A high colour-index may also be present. Recovery may take place.

A review of the literature supports the view that arsphenamine (606) is not the culpable arsenical preparation, but that neoarsphenamine and sulpharsphenamine are the responsible ones (see Table I). A corresponding

TABLE I

Reporters	Preparation	Lesion	Result

reaction has not been seen subsequent to arsphenamine therapy. The purpuric-anæmic syndrome may follow either intramuscular or intravenous injections.

Two factors are possibly at fault for the development of this syndrome. The first is the influence of arsphenamine on the coagulability of the blood. Flandin and Tzanck¹⁶ believe that arsphenamine disturbs the normal coagulability of the blood by its action on thrombin or its precursors. They report that the coagulation time may be prolonged to 30 minutes and upwards following the intravenous injection of arsphenamine, and that this state may last several hours. They also consider arsenobenzol superior to citrate as an anti-coagulant for indirect blood transfusions. Trost¹⁷ in 1923 published similar views. In the United States Public Health Service, in experimental work on animals after the injection of neoarsphenamine the vein must be tied as profuse bleeding has been known to occur. The same regulation does not hold for arsphenamine (Schamberg¹⁸).

It is a common observation that with the reduction of the blood platelets below 60,000 per cmm that hæmorrhagic purpuric lesions develop, which provides an additional etiological factor.

That neoarsphenamine and sulpharsphenamine exert a toxic action on the bone marrow has been generally accepted. All blood elements are thereby affected. In a fatal case reported by Moore and Foley¹¹ such degenerative changes were seen at necropsy. The marrow was definitely aplastic and showed signs of exhausted activity. A striking feature was the absence of mature forms of the leucocytic series. In another fatal case recorded by Moore and Keidel,¹² with the microscopic study by Dr W. G. MacCallum, it appeared that the bone marrow of the femur had ceased entirely to produce the elements of the blood. In short, these arsenical preparations exert a direct destructive action on leukocytes, platelets and red blood cells. The interference with the platelets makes the hæmorrhagic diathesis and the leukopenia and anæmia result from the toxic action on the other elements, namely, the white and red blood cells.

The similarity of the blood picture and the bone marrow lesions to that seen in cases of benzol poisoning is noteworthy. Selling¹⁹ de-

scribed the latter intoxication. In neoarsphenamine there is a double benzol ring. Auberton² believes that it is the benzol radical that is responsible for the pathological process. Moore and Foley¹¹ state that the most satisfactory theory is that there is some impurity in the drug, or that, under unknown circumstances, it breaks down in the body into some compound that produces the reaction. The case here reported and also the one described by Smith¹⁰ rather dispels the idea of impurity, since on two separate occasions a hæmorrhagic diathesis developed, different ampoules of neoarsphenamine were used, and no other reactions occurred in other patients under treatment at that time.

The rarity of the lesion is striking. Our case, described above, is the first observed in this hospital where there is an annual admission of 19,000 patients to the wards and out-patient department.

TREATMENT

Prevention is, as in many other instances, the best remedy. The occurrence of mild nitritoid symptoms and slight purpuric lesions are a prodromal indication. Jaundice may also appear in like manner. In such cases arsphenamine and other antiluetic remedies can be safely used and should be substituted. As neoarsphenamine and sulpharsphenamine are arsenical preparations sodium thiosulphate intravenously is indicated, in increasing doses from 0.15 to 0.6 gm in 20 per cent aqueous solution daily. In cases that develop a progressive anæmia repeated blood transfusions have been life-saving. These enable the patient to live while the toxin is being eliminated and the blood centres are thereby given a chance to regain their function. This process is usually slow except in young adults. Weil and Isch Wall⁴ note that with transfusions convalescence is often obtained without relapse, but that in pernicious anæmia transfusions are of no ultimate benefit.

RESULTS OF THE OPERATIVE TREATMENT OF DUODENAL ULCERS IN A SERIES OF CASES

By J. A. MacFarlane,

Department of Surgery, University of Toronto

Toronto

THERE exists at present a considerable difference of opinion as to the value of various types of operation for chronic duodenal ulcer, and it was thought that it might be of some interest to endeavour to ascertain the late results in such cases in the public wards of the Toronto General Hospital.

The five-year period, January, 1921 to January, 1926, was selected, so that all cases reported must have been operated upon at least two years. The operations were performed by the various members of the surgical staff of the Toronto General Hospital, and the results are those of the surgical service as a whole rather than of any individual group.

During this five-year period 64 cases of chronic duodenal ulcer were operated upon in the public wards. It has been possible to trace only 48 of these cases, or 75 per cent. Of the cases traced those living in Toronto were seen and interviewed, and the large proportion of them were examined radiologically by Dr. Dickson. Those living outside the city, who have been noted as having been traced, reported through a questionnaire.

In the series there were 13 women and 51 men, being 20 per cent and 80 per cent, respectively. The average age of the women was 37, the average age of the men, 41. The ages at operation varied from 16 to 60 years. The average of duration of symptoms was 10 years, varying from 6 months to 40 years.

There were four post-operative deaths in the

series. In one case the man died of hæmorrhage and in another, the cause would seem to have been hæmorrhage, but there was no post-mortem. In the other two cases the cause of death was broncho-pneumonia. There was one death occurring four years after operation. This man died of acute small-bowel obstruction but had evidently been perfectly well until the onset of the fatal illness.

The following types of operation were carried out—

	Cases
1 Simple gastro enterostomy	17
2 Gastro enterostomy and appendicectomy	20
3 Gastro enterostomy, appendicectomy and cholecystectomy	2
4 Gastro enterostomy, appendicectomy plus some local treatment to the ulcer, e.g., excision or cauterization	15
5 Pyloroplasty (Mayo Type)	7
6 Pyloroplasty (Finney Type)	3

In order to tabulate results it was thought advisable to divide the cases into four groups.

1 *Recurrences*—These were cases that were definitely proved to be such, either by x-ray, hæmorrhage, or subsequent operation.

2 *Completely Cured*—These people admitted without any qualification that they felt completely well, and those who were submitted to x-ray showed no pathological state.

3 *Greatly Improved*—In this group have been placed those people who are to all intents and purposes cured, that is, their economic disability is nil, but who complain at intervals of vague digestive symptoms, chiefly gas following the

taking of food and some degree of constipation. In those who were x-rayed there was no evidence of recurrence.

4 *Improved*—This group had lost, to some degree, their old symptoms of indigestion, but were not able to carry on with the same work as before operation. They did not regard them-

In Group C there were, in all, 10 cases, and of these 9 cases traced. There was one recurrence. This man had a recurrence of his indigestion within eighteen months. He went to a clinic in another city where a positive radiological diagnosis of ulcer was made, and where he had a posterior gastro-enterostomy done.

TABLE
RESULTS OF VARIOUS GROUPS OF OPERATIONS

	Group A	Group B	Group C
Number of Cases	39	15	10
Traced	28	11	9
Recurrence	2 (7 per cent)	1 (9 per cent)	1 (11 per cent)
Completely Cured	14 (50 per cent)	6 (54 per cent)	4 (44 per cent)
Greatly Improved	8 (29 per cent)	2 (18 per cent)	2 (22 per cent)
Improved	1 (4 per cent)	0	2 (22 per cent)
Dead	3 (10 per cent)	2 (18 per cent)	0

selves cured. In many cases home conditions were very unfavourable.

For purposes of analysis the operations done were divided into three groups.

A Simple gastro-enterostomy, gastro-enterostomy and appendicectomy, gastro-enterostomy, appendicectomy and cholecystectomy.

B Gastro-enterostomy, with or without appendicectomy, plus some local treatment of ulcer, *e g*, cauterization, etc.

C Pyloroplasty (Mayo or Finney Type).

Of the first group there were, in all, 39 cases, and of these 28 were traced. There were two recurrences, being 7 per cent of number traced. Of these one recurrence was in nature of a stoma ulcer, which perforated and was operated upon as an emergency, the perforation being closed. He has been well since. The second man had a recurrence of hæmorrhage, and ultimately developed insanity and is at present in an asylum.

Fourteen cases of the 28, or 50 per cent, came under the group of completely cured, 8 cases, or 29 per cent, were greatly improved, and there was 1 case in the improved group, 3 cases died (all these were post-operative deaths).

In Group B there were, in all, 15 cases, and 11 of these was traced. There was 1 recurrence, being 9 per cent of the number traced. This man had a recurrence of hæmorrhage, has been operated upon since that time, a transection of the stomach being done, and has had hæmorrhages on two or three occasions since his second operation. Six cases, or 54 per cent, were placed in the group as complete cures. Two cases, or 18 per cent, were placed in group three, as greatly improved. There were two deaths in this number, one being a post-operative death, and the other case dying of intestinal obstruction four years after the operation.

If one adds, then, in each group the completely cured and the greatly improved the results in each case stand as follows—

	Per Cent
Group A (Simple gastro-enterostomy, etc.)	79
Group B (Gastro enterostomy and some local treatment to the ulcer)	72
Group C (Pyloroplasty)	66

There were 14 cases who had presented varying degrees of stenosis prior to operation. The operations in these cases were—In 12 cases, a simple gastro-enterostomy, in 1 case, a gastro-enterostomy, with Balfour cauterization of the ulcer, in 1 case, a pyloroplasty.

Of the 14 cases, 2 were untraced, 11 were completely cured, 1 case was greatly improved.

There were 14 cases who had presented symptoms of hæmorrhage before operation. Three of these were not traced, 1 died (post-operative), 1 recurred, the recurrence being in the nature of a hæmorrhage (this case had a simple gastro-enterostomy), 9 are well, either completely cured or greatly improved. None of these nine has had any further hæmorrhage.

RADIOLOGICAL SURVEY

One is indebted to the Radiological Department of the Toronto General Hospital and personally to Dr W H Dickson, for this particular part of the work.

Twenty-eight cases in all were brought back for radiological investigation. Of these 23 had had a gastro-enterostomy performed. In none of them was there any evidence of recurrence, or activity of the ulcer in the duodenum, though evidence of scarring was noted. Neither was there any evidence of a stoma ulcer.

In 22 cases, the stoma was noted as functioning "extremely well," "very well," or "fairly well." In one case, where a gastro-enterostomy

been performed, there was no stoma seen at this examination

Of the 22 cases noted above, in nearly every case 90 per cent of the meal was seen to pass from the stomach by way of the gastro-enterostomy opening

In five cases of pyloroplasty examined by this method, there was no evidence of recurrence or of any six-hour delay, but Dr Dickson noted in every case a hyperperistalsis of the stomach and in his opinion they emptied the stomach against a certain amount of resistance

CONCLUSIONS

1 Operative treatment has given eminently satisfactory results in 75 per cent of all the cases traced. A further small percentage (7) were greatly improved

2 Gastro-enterostomy would seem to have given slightly better results than gastro-enter-

ostomy plus local treatment of the ulcer. Both of these procedures were definitely better than pyloroplastic operations

It must be borne in mind that simple gastro-enterostomy was the operation of choice in those cases which had developed stenosis, and it is an accepted fact that such cases do exceptionally well with such treatment

3 Where the stoma is properly placed, it evidently continues to function for periods of two to seven years as shown by the radiological examination in these cases. It has been the impression of some teachers that following the healing of the ulcer the gastro-enterostomy ceased to function

4 In a limited number of cases, pyloroplasty, of either the Mayo or Finney type, did not seem to give as satisfactory results as the older operations

VESICAL FIBROMA

BY EMERSON C SMITH, M D

University of Alberta,

Edmonton

NON-PAPILLARY benign tumours of the bladder are, according to the literature, uncommon. The usual types of this tumour are, fibromata, myomata and fibro-myomata. The first are very rare. Koll¹ collected 38 cases of so-called "fibroids," 35 were myomata or fibro-myomata, and 3 were fibromata. A search of the literature reveals one other fibroma, reported by Latzko²

The following case is one of fibroma of the bladder. It is interesting on account of the rarity of this type of tumour and also because of the method of treatment employed

CASE REPORT

Mrs L, aged 32, admitted to the urological service of the University Hospital on March 4th, 1927

Complaints Dysuria and hæmaturia

History of Present Illness She stated that for the past four years she had had intermittent attacks of dysuria, frequency, and hæmaturia. These attacks came on at irregular intervals, and usually lasted from three to seven days. During the intervals she was without symptoms. The usual attack consisted of a marked desire to void, and was followed by bearing-down pains and, later, hæmaturia. Rest in bed and opiates gave relief in time. The family and personal history revealed nothing of importance

Physical Examination A well-developed and well-

nourished female of about the age stated, in no apparent pain or distress. All the systems, except the genito-urinary, were negative on careful examination

Genito-urinary System No costo-vertebral tenderness, right or left, the kidneys were not palpated, no tenderness along the course of the ureters, no suprapubic tenderness. Pelvic examination showed the uterus and adnexa to be normal

Laboratory Findings Urine, clear, amber, acid, specific gravity, 1016, albumin, negative, sugar, negative. Microscopically, occasional red blood cells, no pus, no casts. Blood count red blood cells, 4,500,000 per c mm, white blood cells, 8,000, hæmoglobin, 90 per cent. Wassermann test, negative. Blood chemistry, non-protein nitrogen, 32 mgm per 100 cc, urea, 16 mgm per 100 cc, creatinin, 12 mgm per 100 cc. X-ray examination of the urinary tract was negative for calculi

Cystoscopic Examination (March 5th, 1927) urethra normal, bladder mucosa not inflamed, ureteral orifices normal in contour and position. Situated one half an inch above and to the outer side of the right ureteral orifice was a tumour mass, the size and shape of a Lima bean. It had the appearance of a solid non-papillary tumour. It was attached by a slender pedicle about three quarters of an inch in length, and was freely movable. It did not bleed easily. There were no other tumour masses present

Diagnosis Non-papillary benign tumour

Operation (March 6th, 1927) Under ether anaesthesia an operating cystoscope was introduced into the bladder. The pedicle of the tumour mass was completely fulgurated, and the tumour removed with a cystoscopic rongeur. The base of the pedicle was re-fulgurated and all bleeding stopped. The remainder of the bladder wall was again examined and found normal. The patient made an

uneventful recovery and was discharged on March 8th, 1927

Pathological Report (By Dr Harold Vango, Department of Pathology, University of Alberta) An ovoid tumour mass measuring $2 \times 1 \times 1$ cm. It is of firm consistency and apparently covered with mucous membrane. A small pedicle 1 cm is attached. Microscopical examination shows a soft fibromatous structure, a portion of which is covered by typical bladder epithelium. The tumour mass is composed of fibroblasts imbedded in a soft vascular matrix, with a few scattered bundles of collagenous fibrils. Scattered throughout the tumour are many mononuclear cells, mostly lymphocytes and plasma cells. These cells have a tendency to a perivascular arrangement. Several large lymph vessels are also present. Vascularity is most marked at the periphery of the tumour. Here the vessels are small with thin walls and resemble vessels of granulation tissue. The central area shows a small amount of fatty tissue surrounding a large blood vessel. There is no evidence of epithelial lined spaces or of muscle content, and therefore no suggestion of Müllerian body origin. Histologically, the structure is a pure soft fibroma, in which has occurred some inflammatory process. The mass shows some evidence of degeneration and stains poorly.

COMMENT

The most commonly occurring tumours of the bladder are epithelial, papillary, villous growths, which probably often originate as the result of chronic irritation and are often benign, but not infrequently occur as papillary carcinoma.

The tissue (or histoid) type of tumours occurring in the bladder may be of a mature, differentiated form, (benign) or of an immature, undifferentiated form (sarcoma). Of the benign type there occur myoma, fibromyoma, myxoma, fibroma, and angioma. Of these, by far the most common are the myomata or fibromyomata. In the latter form, the connective tissue is a questionable part of the tumour growth and is possibly only stroma. Pure fibromata are rare, as is evidenced by careful review of the literature, in which we could find only four such cases, and this report adds one more.

Fibromata are divided into two groups: 1 Fibroma durum (hard fibroma), 2 Fibroma molle (soft fibroma).

The former shows on section thick closely packed bundles of fibres, poor in cells and nuclei. The soft fibroma shows very loose delicate fibrillar threads and is rich in cells and nuclei. Here the maturity of cells is only approximated and the tumour therefore shows a certain atypical behaviour in growth, and is more likely to undergo sarcomatous growth, or recur after removal.

The various types of the so-called "fibroids" of the bladder do not vary in respect to symptomatology or treatment. The myoma and fibromyoma are likely to attain and do attain greater size. Kusnetzka, as reported by Kostjurin, had a case in which the fibromyoma weighed 9,200

grams. Fibromata do not attain a large size. They may undergo certain changes such as calcification, or necrosis, or cavities may form and become cystic.

The symptoms vary with the type, location, and size of the tumour mass. Those in the fundus, or with short pedicles, may be symptomless and only found during routine examination or post-mortem. Those nearer the bladder neck, or with long pedicles, may undergo torsion or interfere with urination, and dysuria, hæmaturia and frequency result. The tumour may be so large that it diminishes the bladder capacity and frequency of urination occurs. There are no symptoms distinctive from vesical papillomata.

The diagnosis is made by cystoscopic examination. The characteristic findings are those of a smooth well-circumscribed tumour mass with a long or short pedicle, which is easily differentiated by its structure from a papilloma. In the differential diagnosis cystic masses must be considered, such as an ureterocele, and adenoma of Müllerian or prostatic origin.

The method of treatment depends on the size and location of the growth and the length of the pedicle. Suprapubic resection in the majority of cases will be necessary. But in the case reported fulguration of the pedicle was quite easily performed and it is apparently the only case on record which lent itself to this particular procedure.

The prognosis to be given in these cases is usually very good, and a permanent cure results after their removal, but it must be remembered that soft fibroma may recur or undergo sarcomatous change.

SUMMARY AND CONCLUSIONS

1 Vesical fibromata are rare. This case brings the total to five.

2 Fibromata are divided into (a) fibroma durum, (b) fibroma molle. The latter are the more likely to recur or undergo sarcomatous change.

3 Symptoms arose in this case from a combination of torsion of the pedicle and interference with the urinary outflow.

4 The case described is one of soft fibroma which was removed by cystoscopic manipulation.

CO-OPERATION OF HEALTH DEPARTMENTS AND HOSPITALS*

By T. H. WHITELAW, B.A., M.B., M.O.H.,

Edmonton

CO-OPERATION of all health agencies in the community, a clear understanding of the part each has to play in promoting and securing the greatest degree possible of health, happiness and prosperity among the public generally, should be the objectives of the different organizations which are here represented. Happiness and prosperity are included with health because no community can be happy or prosperous which has a low standard of general health. The economic loss entailed by disease, sickness, and ill health is incalculable. The increasing cost to the individual, and to the public generally, of medical service including hospital charges makes it all the more important that that service should be so efficient as to reduce to a minimum the number of days of incapacity and bring about the restoration to health in the shortest possible time. This aspect of the situation should be stressed in dealing with the public, in order to counteract, as far as possible, the tendency to delay in calling in the aid of medical services on account of the expense or financial obligation involved. The owner of an automobile, if he is wise, when he observes some squeak or adventitious noise about the mechanism of his car, or any failure of its parts to function properly, does not delay in having it examined by an expert mechanic. In this he at trifling expense often prevents more serious developments, which may be very costly and may involve grave danger to life or limb. The same owner often fails to take the same care of the mechanism of his own body when he becomes conscious of its lowered efficiency. The periodic examination of individuals apparently well, now so strongly advocated by the American Public Health Association, has much to commend it and is fortunately being increasingly adopted as a means to prevent at its inception a decline in health or efficiency.

The combination of the Health Officials'

Association with the Hospitals and Nurses' Association effected last year, and our meeting together as associated organizations in the interests of humanity, are a happy augury of what the future holds out in health service to the community. Health officials in the past have possibly devoted their energies and limited their endeavours too exclusively to the prevention of communicable disease. The tendency at present is to widen the scope of diseases in which health departments have a definite interest. At recent meetings of the American Public Health Association, the prevention of cancer and heart disease were included in the program for discussion, and the Health Department of New York State has definitely taken up the control of cancer as one of its functions. On the other hand, the medical profession and professional nurses, as well as hospital authorities, have perhaps given their attention too largely to the cure or alleviation of diseased conditions, without giving much time or thought to their prevention where possible.

During the last year a committee of members of the American Public Health Association has sent out a letter and questionnaire to 247 health officers of cities, and to 1,365 general maternity and children's hospitals in the 247 cities represented. The object was to obtain information regarding the relations between health departments and hospitals, and under this heading a preliminary report from this committee is given in the March number of the *American Journal of Public Health*. No specific recommendations are made at present. It is my purpose later to refer briefly to some things in this article and to indicate how far we have gone in Edmonton in adopting some of the ideas there indicated as advantageous, limiting my remarks to municipal hospitals for the isolation and treatment of communicable diseases.

It is a matter of history that it was only forty years ago that in England contagious disease hospitals were built on an extensive scale, with the expectation that hospitalization would con-

* Read at the Conjoint Section of the meeting of the Hospitals and Nurses' Associations and the Health Officials' Association of Alberta, at Calgary, June, 1928.

trol the acute infectious diseases That expectation has not been realized, as there has been no significant decrease in the morbidity rate, especially of scarlet fever, though the mortality rate has unquestionably been lowered While it is probably correct to say that this has been our experience also, it is nevertheless very important that municipal hospitals for the treatment of communicable disease should be provided in all communities, including the rural ones, for the following reasons

1 Because of the lack of proper facilities for isolation and treatment in the average home, this is particularly true of the rapidly growing cities and towns of western Canada,

2 Because of the difficulty of having quarantine regulations properly observed at home, and the increased danger of communicating the disease to other members of the family not already infected,

3 Because in a well designed and conducted hospital we may more closely approach absolute isolation and keep the patient under conditions more likely to prevent complications arising,

4 Because by removing the patient from the home prolonged inconvenience to the well inmates, and financial loss from interference with occupation and social intercourse may be avoided or minimized,

5 Because medical or surgical cases in general hospitals not infrequently are incubating some infectious condition when admitted, which when it develops is a menace to other patients unless the patient is promptly removed and isolated This it should be possible to accomplish without endangering the patient's welfare, or unduly interfering with the continuation of the medical or surgical treatment being given This situation can be best met through having in the same neighbourhood a properly equipped isolation hospital to which all such cases can be transferred

It is a matter of experience that the prompt removal of a case of diphtheria or scarlet fever from a home very frequently means the protection of other inmates and the limitation of the disease to the individual removed With measles, chickenpox, mumps, or whooping-cough, however, this is not the case, as all susceptible cases are usually in the incubation stage before the first case is discovered or removed In well conducted hospitals, moreover, it has been

demonstrated that the death-rate is usually less than half what it is among cases treated at home We have only to visit the homes of the poorer classes, from which the majority of our patients come, to realize why this should be the case Both from the standpoint of the patient himself and the community generally it is advantageous that the majority of our cases, excepting the minor diseases, should be treated in an isolation hospital equipped and conducted in such a manner that the patient himself not only receives the best of care and treatment for the particular disease he has, but is protected against acquiring other diseases which are being treated, or which other patients may bring into the institution impossible of diagnosis at the time of admission During 1927 our isolation hospital cared for 92 per cent of scarlet fever and 90 per cent of diphtheria cases with most satisfactory results Of 5½ cases of smallpox 33, or 61 per cent, were also provided for in a specially isolated ward This arrangement for the care of smallpox is very satisfactory and absolves the Board of Health from the heavy expense of providing for smallpox in a separate building as was formerly thought to be necessary Now that our Public Health Act permits of quarantining and treating smallpox cases in the home at the discretion of the Medical Officer of Health, we expect to be able to handle smallpox satisfactorily with this small isolated ward of four beds, unless unfortunately an epidemic of unusual proportions should develop In following this course we are not unique apparently, judging from the report on this matter by the committee of the American Public Health Association already referred to, which is worded as follows, "Not the least significant of the entrance of the private hospital into this public health field is the number which receive smallpox—a situation which seems to presage the doom of the pest house"

While an isolation hospital does not need to provide accommodation to any great extent for measles, chickenpox, mumps, and whooping-cough, of which usually too limited a number will apply for hospital treatment to make it necessary to provide special wards for their reception, the responsibility nevertheless exists to provide for an occasional case of these diseases Many young men and women of our cities live as individuals in hotels or rooming-houses, the

latter of which afford no means of getting meals or food on the premises. Because of this, and because of the impossibility of obtaining proper treatment or isolation of cases of the minor infections which not infrequently develop among young adults who have not developed immunity previously, the absolute necessity exists of removing them to a hospital, and the only hospital which can or will receive them is an isolation hospital. For such individual cases a series of small wards should be available, and all the necessary precautions taken to prevent cross infection, by careful nursing and the practice of medical asepsis. The ideal hospital, which on account of excessive cost of construction and maintenance would seem to be unattainable in smaller cities, would necessitate the provision of a separate ward for each patient, on admission to which he could be kept a sufficiently long time to cover the incubation period of any other disease he might possibly be incubating. This alone would prevent or reduce to a minimum the possibility of cross infection. Usually too limited a number of such individual wards are available, as is the case at our Edmonton hospital, to make it possible to carry out this period of detention in single wards, except in a minority of cases. The six wards we have have proved to be very useful in treating the odd case of erysipelas and isolating any case in which the diagnosis had not been definitely established. A considerably increased number of these detention wards in the construction of this otherwise admirably designed and efficient hospital would have more closely approximated to the ideal suggested.

Time will not permit of going into details as to the construction or management of isolation hospitals. Suffice it to say that cross infection is now controlled and prevented by following out the well-known routine of medical asepsis as practised in modern hospitals, with the emphasis on personal contact as the chief cause of communication of disease, and a careful technique and strict discipline as applied to the nurses, physicians, attendants and employees.

In some cities the hospital for communicable diseases is under the control of the Medical Officer of Health and operated independently of other hospitals. This does not commend itself either as an economical method or as likely to give the best service. In Edmonton the best

type of co-operation between health departments and hospitals is in operation, since the management of the isolation hospital has been transferred to the city-owned general hospital, the Royal Alexandra. The advantages of this form of co-operation and the general principles which should govern both parties to it are so well expressed in the report of the committee of the American Public Health referred to that I take the liberty of quoting from it as follows:

"The utilization by health departments of private general hospitals for the care of acute communicable diseases is now recognized as a sound policy which holds advantages for both groups. For the health department these are chiefly (1) The economy in the cost of controlling disease, and (2) provision of better service.

"The hospital derives advantage from the arrangement due to (1) The broader service it can offer internes, (2) the student nurses being able to receive desirable experience in this special field at their own institution instead of being sent to other hospitals, and (3) payment from public funds for patients with communicable diseases who are unable to pay or are hospitalized against their will.

"The numerous and successful instances of co-operation in this field suggest their desirability and community value. In the development of such programs it should be recognized that in the hospitalization of communicable disease the responsibilities of the health department relate primarily to approval of quarters, equipment, etc., and to the admission and release of patients but do not extend to administrative responsibility within the hospital."

For satisfactory co-operation therefore the responsibility for admission and release of patients must necessarily rest with the health department, which, however, exercises no direct authority in the internal administrative control, which is the function of the hospital authority. On the other hand, the health department must depend on the hospital authority to provide adequately for all cases of communicable disease where hospitalization is necessary.

Further advantages of co-operation of health departments and hospitals are suggested in this committee report, where the health department obtains laboratory service from the hospital, or the reverse, where the hospital uses a health department laboratory equipped and provided by the municipality. In Edmonton at the various large general hospitals fully equipped laboratories are provided, but only that of the municipally owned Royal Alexandra Hospital is utilized to the extent of handling the laboratory work of the patients treated in the isolation hospital attached. For many years the health department has been utilizing the service

supplied by the Provincial Laboratory of the University of Alberta

Another form of co-operation between health departments and hospitals is the establishment of clinics at the latter. The simplest form of co-operation is where the hospital furnishes the quarters and equipment while the health department provides some or all of the medical, dental, nursing, and clerical service. There may be complete control of the clinic by the hospital, with the health department merely co-operating in public health relations or assisting by a financial subsidy, or the other extreme, where the hospital furnishes only the quarters and the health department provides everything else, including service, drugs, etc. Such co-operation is at the present time confined to the larger cities, where fully organized health departments

are established and large well equipped hospitals exist. In Edmonton the necessities of the situation are sufficiently well met at present through the operation in the down-town area of the Provincial Clinic, which is carried on under the supervision of the University Hospital staff. To this clinic the city of Edmonton makes an annual grant of \$100 towards the upkeep of the dispensary, which supplies medicines for relief cases.

In conclusion, I desire to emphasize the necessity of co-ordinating for public service all the health agencies at work in our communities. All petty rivalries should be eliminated, and co-operation, continuous not sporadic, voluntary not compulsory, should be for mutual advantage, the goal of our attainment.

THE RELATION OF THE PRACTISING PHYSICIAN TO PUBLIC HEALTH ACTIVITIES*

BY JAMES WALLACE, M A , M D , D P H ,

*Associate Field Director, American Public Health Association,
New York City*

CONSIDERABLE discussion has taken place in the last few years as to the relationship of the medical profession to public health agencies, official or non-official, and more has been said than has appeared in print. The activities of certain agencies have been interpreted in a few localities as suggesting state medicine, and where this has happened the usual harmony and co-operation between the medical profession and these agencies has been disturbed. A health officer not long ago remarked to me that these differences arose only in communities where the public health agencies were aggressive and the medical profession conservative and unsympathetic toward anything that suggested modernism. I will not discuss whether some of these health agencies loved and pursued some objective not wisely but too well, as I think has happened in some cases, nor will an attempt be made to discuss whether there are countries or communities where something approaching a form of state medicine may not

be advisable. That subject is left for consideration by those who are competent to deal with it. Personally, I am as much opposed to state medicine, as the term is ordinarily understood, as physicians generally are, but for the carrying out of legitimate public health projects, in my opinion, no encroachment on the province of the physician is necessary, and so far from begetting opposition should result in mutual helpfulness. My purpose is to indicate how essential the practice of medicine and the promotion of public health are to a community, and that they are not enemies or opponents but partners in building up and keeping in repair the community's health. As Dr. Arthur Dean Bevan,¹ Chairman of the Council of Medical Education in the American Medical Association, said last month at a meeting of the Council, "Medicine has become one of the greatest functions of modern civilization. It is in everyday contact with every individual in the community. Without modern scientific medicine, without modern public health service, our civilization would cease to exist. Great cities such as London,

* Read at the annual meeting of the Ontario Medical Association, Kingston, June, 1928.

New York, Paris, and Chicago would be impossible." What has helped to make possible great cities is also essential for rural communities even though the less density of population does not make the need so apparent. Dr. J. G. Fitzgerald, of Toronto, recently referred to this in an address² on "The future of public health," in which he said, "The conduct of organized public health work is now too largely confined to the populous centres, the safeguarding of the lives of mothers and little children should not be contingent upon residence in a city or large town."

The thought that the practising physicians and health workers are co-partners leads me to say that, in my judgment, of all the many agencies contributing to the up-building of public health, consciously or unconsciously, directly or indirectly, the physicians as a whole are making the largest contribution. The statement is made notwithstanding the remark made recently to me by a State Health Officer, who stands very high in the medical profession, when asked what he considered the outstanding public health problem in his state. His reply was "The education of the physicians as to the significance and importance of public health work." Having said all this, let us ask what we mean by the practice of medicine and what we mean by public health.

The new International Dictionary defines Medicine as "The science and art of dealing with the prevention, cure or alleviation of disease, in a narrower sense, that part of the science and art of restoring and preserving health which is the province of the physician as distinguished from the surgeon and obstetrician." Such a definition definitely makes *prevention* as well as *cure* a part of the function of the physician.

It was only to be expected that medicine and the function of the physician would be taken in a more restricted sense until the discovery of the causative agents of disease. As long as disease was considered an individual matter, without a knowledge of how causative agents may be passed from man to man or how a common cause may affect great groups of people, it was only natural that attention would be centred on the individual. The individual needed relief and little thought was given to conditions or agencies lying behind his illness that might result in striking down others of his

fellows. In the absence of a knowledge of the causation of disease, medicine and its practice became largely individualistic and the physician's part was conceived as being treatment of disease in the individual. Where our knowledge of the origin of disease is still limited to its symptoms in the individual this is still largely the rôle of the physician. With the discovery, however, that many diseases attack us through our contact with other living things, mostly man, or develop through our occupation or environment, or through a deficiency of the food we eat, or in some other way, our conception of the range and scope of medicine and the function of the physician has greatly expanded.

What on the other hand is public health? The breadth of the subject makes it difficult to define. Professor Winslow³ of Yale defines it as "The science and the art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organizing of nursing and medical service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will ensure to every individual a standard of living adequate to the maintenance of health, organizing these benefits in such fashion as to enable every citizen to realize his birthright of health and longevity." An attempt to furnish a briefer definition has recently been made⁴ by a committee appointed to make a census of health workers. They say that for the purpose of the census "Public Health Work shall be defined as those activities carried on by the individual himself or in connection with an organization, supported either by public or by private funds, this work to be directed primarily towards the prevention and control of disease, the promotion of hygiene, and the prolongation of life, rather than the cure of the already sick individual." Public health, it will be seen, is taken to represent a much wider field than that of medicine, including within its activities many workers not usually associated with medicine, such as the sanitary engineer, the veterinarian, the plumber, the statistician, the epidemiologist and the bacteriologist. Of course medical men, too, make use of the services of those who strictly speaking are non-

medical, such as radiologists, bacteriologists, chemists, and others. Some think many of these branches rightfully belong to medicine. Indeed as Dr. Rufus Cole⁵ recently pointed out "medicine occupies a peculiar position among the sciences. By workers in other fields of science medicine has been looked on askance, even disregarded, it has been even claimed that there is no such thing as a science of medicine. On the one hand, as medicine, it has been scorned and neglected, and on the other, as the medical sciences, it has been honoured and respected and held to embrace within its borders such important divisions of science as anatomy and physiology." Whatever medicine is supposed to embrace, almost from the very first, when it was as yet groping in darkness after the light, and while there was as yet no true conception of its scope and significance, it was recognized that the healing art was not a thing apart from what little was known of prevention. From the first, assistance was sought by the medical practitioner from sources other than those that were purely medical. For was not Æsculapius himself supposed to have legendary children, Hygieia and Panacea who assisted in the temple rites and fed the sacred snakes? With our increased knowledge of the causation of disease there has come a new and very definite conception of prevention and the place that it ought to occupy in the thought and program of the medical practitioner, as well as in the thought of all others who are desirous of promoting the common good. Dr. F. H. Garrison⁶ in the closing sentence of his *History of Medicine* states that "The aim of modern medicine, co-ordinate with the advancement of all the sciences, is the prediction and control of phenomena, the *prevention* (italics, the author's) as inclusive of the cure, of disease." Sir Arthur Newsholme⁷ recently pointed out that there are some diseases for which we cannot draw lines of demarcation between treatment and prevention, the one necessarily runs into the other. Such are tuberculosis and venereal disease, and to a lesser extent maternal care and the care and feeding of children. The chief business of the medical practitioner is to guide the sick to recovery, but he also has a duty in "the wider contact with society in the prevention of disease."

With the growth of the idea of prevention and the conception of its possibilities, there has

arisen a new sense of communal responsibility, so that not only the medical profession, but all health workers, official or non-official, feel in some way responsible for responding to the call for preventive action, in order that the pestilence which has walked too long in the darkness and the destruction which has wasted too long at long at the noon-day may be banished from the land. Descartes remarked long ago that we could be freed from an infinity of maladies both of body and of mind if we had sufficient knowledge of their causes and of all the remedies with which nature has provided us. We have not yet complete knowledge of either the causes or the remedies, but we have sufficient knowledge of the means of prevention to make it possible to prolong life, reduce illness, and make happiness more universal. According to the estimate of an eminent statistician, 33 per cent of all deaths are due to preventable disease, not to mention the inestimable amount of illness that does not at least immediately result in death. The physician of a few years ago might limit himself to curative medicine, and feel that in so doing he was fulfilling his mission as a practitioner. There is now however an ever-increasing demand by patients not merely to be cured of present illnesses, but for instruction in methods of preventing recurrences in themselves or in their families. Besides, as Dr. H. S. Cumming, Surgeon General of the United States said at a conference of officials of the American Medical Association and public health workers in March, 1927⁸ "People are interested in obtaining health, rather than in the method of obtaining it, and the medical profession must recognize this." The public as a whole is not interested in the present or the future of the medical profession and if the information that it seeks for its own protection and its family's protection is not forthcoming from the physician the public is likely to turn elsewhere for it. Unfortunately it too often turns to some cult or professional advertiser, that makes far reaching claims or it may seek counsel from the professional educator a type of person who, as I heard Dr. W. I. Mayo remark recently was "a good person to go to for information, but a poor person from whom to seek advice."

The conservation of health is a great economic problem, challenging the best thought and action of the people of to-day. It is, as Disraeli said, "the foundation on which reposes the

happiness of the people and the power of a country." Disabling disease is costing, on a conservative estimate, the United States annually \$2 000,000,000. The decrease in efficiency is estimated at another \$1,500,000,000, while the loss through premature death adds an additional \$6,000 000 000. We cannot grasp the magnitude of such figures, but they are sufficiently impressive to indicate that the public will not any longer be satisfied unless every reasonable effort towards prevention has been put forth to reduce or wipe out losses that are needless and avoidable.

People now know that public health measures can prevent disease. They have reached the position anticipated by Lord Palmerston," the Home Secretary of England in 1853 when at that time with the oncoming of spring it was thought an epidemic of cholera would occur. The Presbytery of Edinburgh wrote Palmerston asking that a national fast be proclaimed. He replied that the best course would be to execute measures to improve the sanitary condition of their towns and root out causes and sources of contagion, "which," said he, "it allowed to remain will probably breed pestilence in spite of the prayers of a united but inactive people." The physician appreciates the remark of Plato that "the poor man cannot afford to be sick," not because of the cost of medication (for medical service is often given free), but because of the loss in time and wages. The thoughtful physician knows full well that it is even more important to curb disease from the communal standpoint than from the individual standpoint. The physician is not only a physician, he is a citizen, so that both his place and his training make the public health a matter of special concern to him. He is usually the best qualified person to give advice on matters concerning the public health, or at least he ought to be. We have to remember, however, that ordinary facts about disease and its prevention are no longer hidden mysteries, or altogether foreign to the laity. There are certain phases of public health work in which the advice of a competent sanitary engineer or a plumber, or a trained health worker, might be of more value than the advice of a physician. Dr Victor C. Vaughan in an address to the American Medical Association, not many years ago, used these words "Many of the more intelligent of the laity know much

more about preventable diseases than some of our physicians." Generally speaking however the physician is the natural leader and the best informed on matters that concern the public health. In all movements and campaigns where the public health is involved, it is the duty as well as the privilege of the medical profession to assume that leadership which its training and experience warrant. "The physician," as Dr Wendell Phillips "President of the American Medical Association stated at the conference already referred to, "is the individual in the community with the basic knowledge necessary for proper public health work." Health programs in a community should not be launched without an effort to secure the co-operation and active leadership of the medical profession, and the initiation and direction of such programs should not have to be wholly assumed by those outside the profession, because nobody within it was sufficiently interested, public spirited, or provident enough, to participate in them. Many movements have suffered because medical men have withheld their co-operation and counsel, the result being that the direction of the movements fell into the hands of enthusiasts who were well-meaning but inexperienced and ill-informed, when a less conspicuous program, based on mature medical experience, would have resulted in permanent benefits.

That the medical man may give the proper advice and be competent to lead or assist in leading such movements, he must first of all be properly schooled himself. If the blind lead the blind they may both find themselves in the gutter. In his medical course the physician has learned the fundamentals that equip him to deal with questions affecting the health of the individual, and to some extent, groups of individuals, but, to quote Sir Arthur Newsholme¹¹ again, "Every physician within the scope of his own medical practice should become a medical officer of health." "There is needed," he says, "a reconstruction of the training of each medical student, which will make preventive medicine in its widest sense an integral part of his training, and will ensure that before he begins practice he has definite instruction in the application of the whole of his knowledge to preventive purposes. The past conception by the public of the relation of medical men to the community, apart from the special case of

medical officers, has been mistaken. The doctor has been regarded as a help when serious or acute incapacitating illness occurs, and he has but seldom had the opportunity of giving advice in the earlier and more controllable stages of illness. His training has been conducted on the assumption that his chief rôle should be on present lines, with the result that most medical practitioners enter into practice with a too scanty knowledge of hygiene and preventive medicine, and have to learn slowly in belated experience the influence of environment on the health of their patients." The blame for this unfortunate experience is not to be laid at the door of the physician, but rather to what in the past the public has demanded of him, and the kind of training he has received. Sir William Osler, with all his interest in curative medicine, stated that every physician who has in any way to do with the public health should be specially trained for it. In speaking of typhoid fever in 1913, he said¹² "How Galen would have turned up his nose with contempt at the water supply of the Dominion of Canada scourged so disgracefully by typhoid fever of late! The health officers should have special training in sanitary science, and special courses leading to diplomas in public health should be given in the medical schools. Were the health of the people made a question of public and not of party policy, only a skilled expert could possibly be appointed as a public health officer, not as is now so often the case, the man with the political pull." All physicians cannot become specialists in public health any more than they can in surgery or pædiatrics. To be a successful health officer one requires to be a good administrator. The kind of technique required here differs from that of surgery, it is the technique of dealing with people, the ability to convince them of the value of a project worth while, the ability to get popular support for such projects, the ability to give publicity to the work being done, in order that the public may be impressed and appropriating bodies made to see that the work should be supported. The successful health officer must also be able to get action without resort to police power, and yet must have sufficient backbone and fighting courage to stand up for what he believes to be in the best interest of his community. Many able physicians shrink from having to assume a post demanding such quali-

fications, but this does not mean that they should not be grounded in the principles of public health work, give it the benefit of their judgment and help to so guide it that it may become the vital force it ought to be in the community. Physicians who are not health officers but who interest themselves in health work can often wield special influence in moulding policies and putting over programs, just because they are not health officers. We are all convinced of the value and necessity of public health work. We may not approve of every form of work that has assumed the name of public health. The number of organizations in which health work is primary, secondary, related or incidental, is legion. There are something like thirty of them in the Federal Bureaus of the United States, while among non-official agencies there are many more.

There has been a good deal of duplication in health work, but with better organized state and provincial health departments, and with better local health organization, there is resulting through the placing of all health work in the local area under the city, county or district health officer, a very decided reduction in the amount of duplication. This placing of all health work under one head, preferably a full-time man not in the practice of curative medicine, tends to uniformity, economy and general efficiency. The better sanitary supervision, resulting in the better control of communicable disease, and the programs of health education have had far-reaching benefits. In the northern parts of this continent we have not had experience of the remarkable results following campaigns against yellow fever, malaria and hook worm, but even with our less evident and less tangible problems of prevention sufficiently marked results have been obtained in reducing mortality, lessening morbidity and absenteeism to impress the least receptive mind. Better health protection has resulted in better economic conditions and greater happiness among the people, for, as W. H. Lecky the historian remarks, "To raise the level of national health is one of the surest ways of raising the level of national happiness."

But are Public Health and those who work at it of any benefit to the physician? Are public health efforts depriving him of his livelihood and is there no off-setting compensation? In

such results are being obtained they are exactly what the physician himself labours to effect, consciously or unconsciously. Dr. W. D. Haggard, in his presidential address to the American Medical Association¹³ in 1925, said "Medicine is the only profession that is literally and altruistically devoted to professional suicide." But, as he went on to add, the fields are still white unto the harvest, the physician's job is as yet unfinished, and if the old line of curative medicine diminishes, a new field is unfolding in the tendency for people more and more to seek the services of the physician to preserve rather than to restore their health. "Physicians," he said, "have been so busily occupied in the care of the acutely sick that they have had little time and paid little attention to those who were in apparent health." Public health agencies have done a great deal in directing the attention of people to the advantages of keeping well. So general now is the thought of keeping well that about 50 per cent of all advertisements have health or keeping well as the basis of appeal.

Public health agencies have been of great assistance to legitimate medicine through not being handicapped in their use of publicity, as physicians have been, because of certain ethical standards of the profession. Many projects of a communal nature require publicity if they are to be accepted by the public. A health officer, for example, who is not in the practice of medicine can make use of publicity in a way that would not be good form or expedient for the practicing physician. Health departments, too, have aided physicians by making laboratory facilities, vaccines and sera available for them, and in providing diagnostic consultant service for cases of communicable disease. A local health department, however, can do a great deal in cultivating and creating public confidence in the local physicians and their work, and in urging more general use of medical facilities. This the practicing physicians themselves cannot very well do. In my judgment, it is no function of a health department to give personal medical service to the public at large. In fact, when work for indigents has to be done, a department of health should only do it when physicians find it inconvenient to do so, or when it is done with the approval of the local medical society. There are deserving

cases that need attention that would be neglected without free service. There is perhaps no other class of professional men that gives as much free service as do the physicians. There is a class of people that, as Josh Billings says, "gets what they can for nothing and values it at what they paid for it." Public health workers, while intensely interested in seeing that the needy get the service they require but cannot pay for, should be careful to avoid propagating pauperism. Programs of immeasurable benefit to a community have been carried out where the health department and the local medical society have co-operated, the physicians doing all the medical work and the health department managing the campaign. In a Western city more than 20,000 school children were given toxin-antitoxin for diphtheria prevention and all the work was done by the local physicians. All families able to meet the cost did so, and for all indigents the physicians did the work free. The result was that more than 95 per cent of all the school children were treated, and almost as large a percentage of pre-school children have since been included. The health department can aid physicians by giving advice to the public as to the inadvisability of wasting time with quacks and patent medicines, and the advisability of having a proper diagnosis made early in suspected cases of disease, and the desirability of the apparently well consulting the physician periodically in order to keep well. Where health departments have to do with school children, they can discover suspected defects and have the children referred to their family physician, and where a nursing service is at work, the nurse can follow up these cases and use every legitimate means to have the parents see that the children are taken to the physician. Thus the health department, instead of supplanting the physician, becomes an indirect agent for him to induce people to have whatever medical or surgical service they need. That the health officer may do this most effectively he should as already indicated be a full-time man, not competing with physicians in practice. Some few part-time men, because of their special fitness or influence in the community, can carry out such programs, but experience shows that they are few in number.

What on the other hand can the physician do

for the health department? If he is public minded and has sufficient training and interest in public health to induce him to identify himself with it, he can greatly assist. He can see that the department has proper contact with the medical profession, through the local county or city medical society. He can see that there is an active committee on public health relations that will serve as a connecting link between the society and the public health department. The local health officer, if a physician (which is usually desirable), should be a member of the local medical society. This will tend to promote mutual understanding and to prevent misunderstandings. In Milwaukee, according to Dr A T Holbrook,¹⁴ a splendid arrangement exists whereby a public health council of fourteen (six physicians and eight laymen) advises the local health department. In the Medical Society of King's County, New York, an active committee serves as a bond between the health department and the physicians. This committee took the lead in promoting health examinations by first examining 91 of the members of their own society. It keeps the society informed on health matters, so that mutual co-operation and understanding result.

The medical society can be of special assistance to health departments in getting moral and financial support. The health departments are often inadequately financed through meagre appropriations, because there is only one voice, that of the health officer, asking for support, and his voice is like that of one crying in the wilderness. If the medical profession, or medical society, would declare itself distinctly and emphatically, saying "We believe it is in the interest of our community and that it is essential for community safety and community health that an efficient, properly equipped, health department be provided," such a pronouncement, followed by personal support, would go far toward getting the necessary appropriations. What appropriating bodies need to be made to see is that the health department is just as important to a community as a fire department. You can destroy every dollar's worth of property in the world by fire, and the human race would survive and rebuild. If you destroy or incapacitate the human race, property would

have no value, and would immediately begin to pass away, never to return. For as Edwin Markham says —

"We are all blind until we see
That, in the human plan
Nothing is worth the making if
It does not make the man,
Why build these cities glorious
If man unbuilded goes?
In vain we build the world, unless
The builder also grows."

Curative and preventive medicine are not two wholly separate and independent entities. In a general way they can be demarcated and differentiated, but they are parts of one whole. They are parts of a properly articulated body of medicine, as surely as the eye or the hand is of the physical body, and if the eye or the hand suffer the whole body suffers with it. Dr Oliver Wendell Holmes said "Charity is the eminent virtue of the medical profession. Show me the garret or the cellar which its messengers do not penetrate. Tell me of the pestilence which its heroes have not braved in these errands of mercy. Name the practitioner whose footsteps are not found in the paths of every haunt of humanity." A noble tribute to a noble profession, but is it not also true that there have followed the physician into those hovels and gloomy alleys, into places of squalor and pestilential disease, the nurse and the sanitarian, to stay or stem the tide of danger, and to pluck from harm's way those who otherwise would be offered as sacrifices on the altars of ignorance, neglect, or disease.

Case Reports

AN UNUSUAL CASE OF ABDOMINAL INJURY IN A CHILD

By H. M. ELDER, M.D.,

Montreal

A boy, aged ten, was admitted to the Montreal General Hospital, (service of Dr. A. T. Bazin), on April 14, 1927, at 4 p.m., having been struck by a motor car. He was conscious and stated that both wheels of the motor car had passed over his abdomen.

Examination revealed a rather underdeveloped and undernourished French Canadian boy, who lay in bed in the dorsal decubitus, and was not apparently suffering very acutely. He had not vomited, and though very pale, was not in profound shock. His temperature was 99.4, pulse 110, respirations 24. Blood pressure was 70/35. There were two superficial scalp wounds in the occipital region, and an abrasion on the left buttock. The chest was resonant and the breath sounds normal. No evidence of fractured ribs could be made out. The abdomen was scaphoid with practically no respiratory movement. There was generalized tenderness, most marked in the right upper quadrant with splinting of the abdominal muscles. Liver dullness was not obliterated and there was no dullness in the flanks. Rectal examination gave no information. The reflexes were normal. White blood cells, 10,000 per cmm. Urinalysis showed no blood, chemically or microscopically.

In view of these findings, and also of the fact that no corroboration of the statement of his having been actually run over could be obtained, he was kept under observation. About six hours after injury, he became restless, and complained of crampy abdominal pain. He also commenced to vomit undigested food, and bilious material, but no blood. He constantly called for the bedpan, expressing a wish to go to stool, but without result.

Examination at this time revealed a slight fullness of the abdomen with the same tenderness as before, but with definite movable dullness in both flanks. His pulse had risen from 110 to 130, and the leucocyte count remained

stationary at 10,000. A tentative diagnosis of ruptured bowel was made, and laparotomy decided upon.

The abdomen was opened by a right paramedian incision and on opening the peritoneum there was a gush of blood. In view of the fact that a diagnosis of ruptured bowel had been made, no attempt was made to preserve this blood for auto transfusion. Exploration revealed a laceration about two inches long in the quadrate lobe of the liver, a laceration along the longitudinal sulcus, and stellate lacerations of the tail of the caudate lobe, all of which were bleeding freely. This hemorrhage was controlled by the insertion of mattress sutures of catgut. The stomach, duodenum, and spleen were examined with negative findings.

The small intestine, which had been noted to be in marked spasm in several places, was then followed from the duodeno-jejunal flexure to the cæcum, and, in the course of this, three intussusceptions were found, the largest being about two inches in length. These were milked out, and the remainder of the intestinal tract and bladder explored, but no evidence of injury was found. A cigarette drain was left in place, with the lower end at the foramen of Winslow.

During the operation the patient received 750 c.c. of 5 per cent glucose saline intravenously, which was allowed to flow as soon as the hemorrhage from the liver was controlled. Immediately on the conclusion of the operation, he was given a transfusion of 350 c.c. of citrated blood, his father being the donor.

After the operation, the patient had a temperature ranging from 100° to 102° F., and a pulse range of 128 to 150. There was a moderate amount of blood and bile draining through the incision, but the bowels responded well to pituitary extract and enemata. There was little vomiting, his fluid intake was fair, and was supplemented by rectal salines.

The convalescence appeared for some days to progress smoothly, though the appearance of a mucous discharge from the wound caused some speculation as to its origin. This discharge, however, caused no erosion of skin, and did not appear to be accompanied by any gastric

secretion Culture showed *Staph aureus* His appetite was good, and his bowels regular On the twelfth day after the operation he was on full diet

On the sixteenth day, May 1st, there was some bleeding from the drainage wound, which had not completely closed In conjunction with this, he vomited large quantities of watery material which was dark brown, and a chemical test showed the colour to be due to blood This continued for the next two days, in spite of the stoppage of all nourishment by mouth, and the administration of hæmostatic serum and morphia On May 3rd, he was given a transfusion of 250 c c of citrated blood, following which the bleeding promptly ceased though he did vomit blood once after the transfusion For the next six days he improved markedly, and was taking a Lenhartz diet, though complaining of occasional attacks of crampy pain after eating

On May 9th he again had a little bleeding externally, checked by hæmostatic serum, but on the 10th, there was severe hæmorrhage, again associated with hæmatemesis, and necessitating another transfusion, which was given that evening and repeated the following morning The day following he again vomited large quantities of altered blood, and there was also bleeding from the sinus He was then given 5 c c of 15 per cent calcium chloride intravenously and after this the vomiting ceased, and the hæmorrhage was apparently arrested, with the exception of one small hæmorrhage on May 14th, unaccompanied by vomiting At this time also there was a discharge from the wound of necrotic material resembling disintegrating omentum The more obvious bleeding appeared to be checked, but as he was so exsanguinated another transfusion was given on May 15th No more fresh bleeding followed this, but there was a discharge of necrotic fatty material associated with a chocolate fluid, and on May 21st, he vomited a large clot of blood Adrenalin 5ss was given by mouth, but with no noticeable effect

Except for a large tarry stool on May 22nd, nothing further occurred until May 24th, when he complained of pain and vomited altered blood There was also bleeding from the wound His condition at this time was very poor pallor, drowsiness, and a rapid thready pulse being marked features For the next four days there

was little change, the patient occasionally vomited small amounts of blood, and the dressings were constantly stained by bleeding from the wound On May 28th, another transfusion was given, followed by some improvement and this was repeated on May 30th

From this time on, he commenced to improve, and, in spite of an occasional hæmatemesis his progress, though slow, was steady The sinus gradually closed, and on June 24th, was entirely healed, and the patient began to improve slowly, and by the end of June he was able to sit up in a chair He was taking a modified Lenhartz diet at this time, and did not complain of pain or discomfort He was discharged to the Out-patient Department on July 14th just three months after admission

When seen on August 20th, he had regained his weight, had a good colour, and looked well The wound was well healed He was taking a normal diet, and suffered no discomfort

SUMMARY

This case is presented, not so much as an example of treatment, as on account of the unusual association of two distinct conditions, and the peculiar complications which arose

It would seem probable, in view of the sequence of events, that there had been either an injury to the duodenum or pyloric region which escaped notice at the time of operation or else the formation of an acute duodenal ulcer with hæmorrhages and perforation It appears impossible to explain the discharge of mucoid material from the wound and the repeated external hæmorrhages, always associated with mælena or hæmatemesis, upon any other grounds

This theory is borne out to some extent by the x-ray examination of the gastro-intestinal tract which was carried out on December 28th 1927 the report of which is as follows —

“Combined fluoroscopic and serial plate examination was made of the gastro-intestinal tract which shows the progress of the meal through the stomach, large and small intestines and colon

“*Diagnosis* — Negative for gastric ulcer and cancer The pyloric end of the stomach is somewhat irregular on the greater curvature side toward the right Cap is irregular and never well filled This is probably the result of adhesions secondary perhaps to traumatism and

operation in this area Stomach empties completely in three hours Stomach quite empty and no appendix seen in the twenty-four hour plate, at which time the hepatic flexure is rather pulled up toward the left "

At this time the boy professed himself as being completely well, was attending school, and living a normal life

A CASE OF CHYLURIA DUE TO FILARIA BANCROFTI, WITH LYMPH VARIX IN THE BLADDER WALL*

By RIDLEY MACKENZIE, M.D.,

Montreal

The case to be described was a negress, aged 28, a native of Barbadoes, West Indies, who came to the hospital complaining of frequency of micturition and cloudy urine

She had been in Canada for two years and her previous health had been good In October, 1926, the first symptoms appeared, which ceased without treatment, but appeared again ten days ago

She was a well nourished young woman The heart, lungs, temperature and pulse were normal, and there were no abnormal abdominal signs The blood count revealed a secondary anaemia, with no eosinophilia Gynaecological examination showed nothing except a retroflexed uterus

Cystoscopic examination—The bladder was tolerant of 500 c.c., with ordinary translucency, the ureteral orifices and the trigone were normal On the posterior wall, just above the projection formed by the impinging cervix, there was bullous oedema with inflammation, with two or three milk white glistening shreds 1 cm. long adherent to the bladder wall These were passed later and were found to be portions of mucous membrane

Examination of the urine—The specimen when passed had a milky consistency, and on standing a precipitate formed, of a pinkish chrome colour The upper layer was opalescent, resembling, as a confière suggested, absinthe diluted with water The specific gravity was 1024, there were no sugar, casts, albumen, or pus cells In the precipitate, which was

largely particles of fibrin, Dr Perrin found the embryonic form of *filaria Bancrofti* in large numbers, coiling and uncoiling A specimen of blood taken from the patient at night showed the same organism in considerable numbers

She was admitted and treated with irrigation of the bladder and instillation of nitrate of silver together with the intravenous administration of salvarsan 0.6 gm. weekly Treatment had no effect on the bladder condition nor on the microfilariae in the blood and she was discharged to report later

Filariasis is a rare disease in Canada and is always imported It is prevalent in the West Indies Australia the east coast of Africa, China and India Sir Frank O'Connor¹ pleads for a thorough investigation into the disease, claiming that 50 per cent of the inhabitants of India suffer from it and that Leprosy causes less misery and a lower mortality

Armstrong and Mullally² of Montreal reported two cases of negresses, who died from other causes and were found to have greatly dilated lymphatic channels in the abdomen, and in one of the cases microfilariae were found in the blood during life Primrose³ of Toronto reported a case of lymph-scrotum due to filariasis After removal adult filariae were found in the specimen by Dr J. H. Elliott In an operation on a broken down mass in the posterior triangle of the neck, six weeks later, apparently other adult worms were removed but the microfilariae disappeared from the blood where they had been found previously in great numbers The disease is not confined to the coloured race Lothrop and Platt,⁴ of Boston, reported two cases in brothers, white, natives of Barbadoes Their report is a fine summary of the subject

The presence of the adult worm in its favourite haunts, namely, the generative organs, and the lymphatic system, brings about a variety of symptoms, abscess, lymphangitis, varicose inguinal glands, lymph-scrotum, lymphatic varix, orchitis, chyluria, elephantiasis, and other forms of disease, from obstruction or inflammation of the lymphatics The attacks of pyrexia are thought to be due to the activity of the embryonal form or to streptococcal infection

The adult worm was first discovered by Bancroft, of Brisbane, in 1876 It is three to four inches long and the thickness of a human hair The female is larger than the male and is

* From the Out Patient Clinic, the Women's General Hospital

viviparous. The embryonic form found in the blood and chyle is about 1/75th of an inch long and as broad as a red blood corpuscle. It is easily found in a specimen of blood taken about midnight and stained with a polychrome stain. Four and five to the drop were found in our case.

It has been estimated that there may be as many as fifty million embryos circulating in the blood, with little or any ill effect to the patient. The general opinion is that the embryo is transmitted after a stage of development in the mosquito, the *Culex fatigans* chiefly.

It is of interest that in 1896 Patrick Manson, because of an observation on filaria by Lewis and Law, suggested to Major Ross that the mosquito might also be the intermediate host of the malarial parasite, as of course it later proved to be.

The term *filaria nocturna* has been applied to the embryonic form, because of its presence in the blood at night, and this peculiarity can be reversed by altering the time of sleeping. The explanation advanced is that the tonus of the capillaries is reduced during sleep and thus the embryos are able to enter the capillary circulation. Manson was able to demonstrate that when the microfilariae are absent from the peripheral circulation they are lodged in the larger vessels, especially in the lungs.

The treatment of this disease, as given in the literature, is primarily surgical, any external manifestations to be dealt with in the hope of removing the adult worm, but the presence of the embryonic form in the blood after many such procedures suggests that unapproachable nests are still left, probably in the large lymphatics. Lothrop and Pratt⁴ found six mature worms in an affected testicle, the removal of which did not lessen the microfilariae in the blood. Almost all forms of the arsenical compounds have been used, also carbon tetrachloride, bismuth, antimony and x-rays. Some slight subsidence has been noticed in the glands under treatment but no effect on the microfilariae in the blood and lymph, as in our case.

We have now in Montreal a fair sized colony of West Indians. The publication of this case may serve to attract attention to the subject and bring about a search for the organism in cases of pyrexia in these people which may help to clear up the diagnosis.

A CASE OF CEREBELLAR ABSCESS*

BY GEO. F. BOYER, M.D.,

Toronto

The following case is deemed to be of sufficient interest to justify the attention of the members of this society.

A S., a boy of seven years, born in England, came to the Hospital for Sick Children on March 5, 1928, with a history of earache without discharge, from February 28th to March 2nd, headache of severe degree for three days, and vomiting for two days.

The family history was irrelevant.

The boy developed normally through infancy and childhood, had had whooping cough at one year of age, measles at five years, and chickenpox at six years. The presence of previous ear discharge was denied absolutely, and, except for an occasional "cold" he was always well. About the middle of February, 1928, he began to complain occasionally of a headache, and towards the end of the month he was noticed to be rather pale at times. On February 27th, he had a slight earache on the right side, but the onset of the present illness was not noted as significant until February 28th, when the earache became much more severe and he was kept from school. The earache gradually became still worse, and on March 1st he seemed "cold all the time." On March 2nd a doctor was called in. The headache had now become severe but the temperature was normal. On March 3rd, the child seemed again to be very well, complained of no headache and was brighter and happier. On March 4th he vomited, but had no temperature on the following day he was extremely ill with headache, vomiting, photophobia and prostration.

CLINICAL COURSE

Examination on Admission—A fairly well-

* Read at the annual meeting of the Canadian Society for the Study of Diseases of Children at Vancouver, June 29, 1928.

developed and nourished male child of about seven years of age, looking acutely ill, with head retracted, temperature, 98, pulse, 116, respirations, 24. He was conscious and complained of occipital headache. Some rigidity of the neck was present, with opisthotonos. Brudzinski's and Kernig's signs were positive. He had no undue irritability or hypersensitiveness, no motor paralysis or paresis, no strabismus or nystagmus. His optic discs were clearly defined in outline, the vessels were normal, and no oedema was apparent on careful examination. The movements of his hands and feet were not accompanied by ataxia. There were no gross changes in deep or superficial reflexes. A slight sero-mucous discharge came from each nostril. He had some carious teeth. His tongue was coated, the tonsils were enlarged and red. He had no post-nasal discharge. There was slight anterior and posterior cervical glandular enlargement. Neither mastoid process was swollen or oedematous. The left tympanic membrane was normal in colour and position, the right tympanic membrane was intact and not bulging, but was slightly inflamed. Bulging was so slight that incision was decided to be unjustifiable. Examination of the heart, chest and abdomen showed no signs of disease. The white cell count was 11,800 per cmm, with 78 per cent polymorphonuclears. Lumbar puncture showed a clear fluid with no definite increase in pressure, having 305 cells per cmm (32 per cent polymorphonuclears, 68 per cent lymphocytes). The Noguchi reaction was positive. A smear showed no organisms. Cultures were sterile at the end of 24 hours.

On account of these findings, a diagnosis was made of diseased tonsils, subacute nasopharyngitis, and otitis media on the right side, with secondary serous meningitis.

On March 6th, after examination by the otolrhological service, the opinion was recorded that he had a "very early acute otitis media of the right side with no post-aural signs whatever." A wide incision was made in the right ear drum but only serum was obtained. The child's general condition was somewhat improved. The highest temperature recorded for the day was 99.1°, pulse, 100, respirations were 22. He was given no antipyretic medication. Tuberculin skin tests were negative.

On March 7th, his general condition was

about the same, but a fine, papular, erythematous rash appeared which soon faded. The highest chart records for the day were, temperature 99.1° F, pulse, 120, respirations, 30. The next day he complained of severe headache, he was conscious, the right ear was discharging freely. Examination of his eyes showed no nystagmus and no optic oedema. Highest temperature, pulse and respirations during this day were 99.6°, 110, 24. A lumbar puncture showed no increase in pressure and a perfectly clear fluid, 29 cells per cmm (9 per cent polymorphonuclears, 91 per cent lymphocytes), positive Noguchi. The smears showed no organism, whilst cultures were sterile after 48 hours.

On March 9th his optic discs were examined by the eye service and were recorded as normal. His highest temperature, pulse, and respirations in the day were 98.8°, 100, 22. Cultures from the right ear showed pneumococcus.

The following day his condition became very much worse. He was complaining of severe occipital headache. His head was retracted but there was less rigidity and Kernig's sign was less marked than it had been a few days previous. The discharge from his right ear continued. He took fluids well and at times said he was quite comfortable. As the day went on his headache and head retraction were more marked. His highest temperature was 99.4°. Tuberculin skin tests were negative. A few cubic centimetres of cerebrospinal fluid were withdrawn by lumbar puncture, great care being taken to keep the head well below the level of the hips, this showed clear fluid, 8 cells per cmm (5 per cent polymorphonuclears, 95 per cent lymphocytes) and positive Noguchi. Smears showed no organisms and cultures were sterile at the end of 48 hours. A guinea pig was inoculated with this cerebrospinal fluid, and one month later was found to show no sign of tuberculosis.

Early in the morning of March 11, 1928, sixteen hours after the lumbar puncture, he collapsed rather suddenly and died.

AUTOPSY

An autopsy, performed a few hours after death, showed the heart to be normal. The lungs, kidneys, liver, spleen and intestinal tract also showed no signs of disease. Examination of the head revealed a normal scalp and skull. The

dula appeared healthy throughout its entirety. No exudate was apparent anywhere. The sinuses were healthy. There was no evidence of thrombosis of veins or sinuses. The cerebral convolutions were somewhat flattened. On removal of the brain, a slight pressure on the right cerebellar hemisphere caused it to burst and exude pus. This had not ruptured until disturbed. An abscess, the size of a large pigeon's egg, was present. This was situated less than one centimetre below the tentorial surface, and was more to the lateral and posterior side than in any way related to the vermis, and it was much closer to the superior surface than to the centre of the cerebellum. Section of the cerebral hemispheres showed no disease in them. The medulla was obviously jammed into the foramen magnum by an increase in pressure within the skull. The pons and medulla were apparently healthy. The mastoid cells on either side were free of disease.

Smear from the right mastoid showed no pus cells and no organisms, and cultures also were negative. Smears from the abscess in the right cerebellum showed a Gram-positive diplococcus, and on culture this proved to be pneumococcus (type IV).

COMMENT

This case shows the difficulty which may be encountered in diagnosing a cerebellar abscess, probably secondary to otitis media, without pyrexia, optic oedema, the cardinal signs of unilateral cerebellar disease, and a falling cerebrospinal cell count, and with many signs suggestive of a serous meningitis.

ANAPHYLAXIS FROM POLLEN INTRODUCED BY A BEE STING

By DOUGLAS F. GIBB, B.A., M.D.,

Oak Lake, Man.

This case is reported because it is rare indeed that one receives a pollen protein test by a natural hypodermic

The patient, a little girl of seven, was playing in her father's garden when a bee became entangled in her hair, and, in its frantic efforts to escape, stung her. On her mother's telephoning me to inquire what to do for the sting I advised

strong soda bicarbonate solution, as that was the only remedy she had at hand. Within fifteen minutes I received a second call this time to come at once. The mother, much excited, reported an almost instantaneous development of severe illness accompanied by "large lumps" over the child's body. When I arrived at their home, a few minutes later, I found the child exhibiting every symptom of a well-established attack of hay-fever. She complained of a tickling and burning in the nasal mucosa, and was sneezing continually, the sneezing being accompanied by a scanty flow of secretion from the nose and eyes. The "large lumps" which I saw were urticarial wheals, were whitish in colour, and very itchy. The catarrhal condition spread rapidly to the pharyngeal mucosa, as was manifested by the onset of coughing, which soon became quite violent and somewhat asthmatic in character.

I gave 1:1000 epinephrine solution hypodermically and sprayed out the nose with normal saline. For the urticarial wheals I used some calamine lotion which I had with me. Soon after the hypodermic the hay-fever symptoms became less severe, and the wheals began noticeably to subside. This improvement continued for about four hours, but about eight o'clock p.m. the coughing began once more to be violent. This time I sprayed the nasal passages with ephedrine inhalant, which soon brought relief. The child sank into an exhausted sleep and the next day was quite well, except for a slight feeling of nausea in the morning.

My explanation for this rather odd case is that the bee had by its sting injected into the child a pollen to which she was sensitive which produced a well-developed attack of hay fever in fifteen to twenty minutes together with the urticarial reaction, much exaggerated of course which appears in a pollen test. Previously the child had displayed no susceptibility to hay fever and was in perfect health at the time she was stung. The lawn and flower garden being her usual playground and the fact that probably all the wind-pollinated plants in the district were past the pollination stage make it improbable that she could have received the irritating protein in any other manner than from the sting. In the week that has elapsed since the attack there has been no sign of any recurrence.

Editorial

THE CHEMISTRY OF TUBERCULIN AND OF THE TUBERCLE BACILLUS

SINCE 1891, when Koch first prepared tuberculin and found that, injected into the bodies of tuberculous animals, it gave a specific reaction, it has been used in the diagnosis of this disease to an extent that is not ordinarily recognized. This extent may be gauged by the estimate, recently made, that more than one hundred million dollars' worth of cattle have been slaughtered in the United States and Canada during the last twenty-five years, because, on test, they reacted to tuberculin. It has, therefore, played a part in the economic field which Koch could not possibly have imagined. Its use in the diagnosis of tuberculosis in the human subject has been very greatly less extensive because the reaction it develops entails, not infrequently, extreme discomfort to the patient, and because also the methods of clinical diagnosis used for suspected cases obviate the necessity, in the vast majority, of resort to the reaction test.

Notwithstanding all the economic and hygienic interests thus involved, no fundamental research work has been done on the nature and composition of tuberculin until four years ago. It was, and still is, as made for the extensive use to which it has been put, derived by preparation from cultures of the tubercle bacilli in boiled beef broth, and it is, in consequence, an "omnium gatherum" containing all the proteins developed by the bacilli in the broth, as well as not a few of the constituents of the latter. This has led one critic to label it "dirty," a term perhaps too severe, but nevertheless not wholly unjustifiable. The product is not and has not been a pure one, containing only the reacting substance, but a mixture, not always uniform, and not infrequently of uncertain standardization.

The explanation for this lack of fundamental research on tuberculin in the past is not far to seek. The technical knowledge necessary for the preparation of the purest product has been of slow growth during the last thirty years, many of those who gave

themselves to work in this line were too limited in their training to achieve any outstanding result, and they merely marked time by contributions on subjects connected therewith of limited interest and evanescent value. The consequence was a "stalling" on the course of progress.

Happily a new era of achievement began about four years ago, when a number of highly qualified technologists began fundamental research, not only on the nature of tuberculin, but also on the composition of the tubercle bacilli themselves. Some of the results so far won are of outstanding importance and they encourage the hope that in a few years more we shall be absolved from the reproach of the past on this subject.

One of these outstanding results has been achieved by Dr. Florence B. Seibert, associated with Dr. E. R. Long, of the Otto S. A. Sprague Memorial Institute of the University of Chicago, who cultivating tubercle bacilli in a synthetic medium devised by Dr. Long, free from protein of any kind and containing only three organic constituents, asparagin, glycerol and citric acid, prepared two years ago from them a quantity of tuberculin, from which she isolated three proteins whose characters, chemical and physical, she determined. She found that only one of these, soluble in distilled water and, therefore, an albumin, can bring out the typical reaction in tuberculous animals. She has continued her work and has recently succeeded in purifying this protein by repeated crystallization, after the method of Hopkins and Pinkus for the crystallization of proteins, from solutions of it at a pH of 4.9. After fourteen crystallizations it gave the maximum tuberculin skin reactions and a typical tuberculin atrophy of the testicle in a tuberculous guinea pig. After the tenth crystallization less than half of it was required to give as strong a reaction as that given by the product of the first crystallization. It is easily denatured, that is, altered in its composition and properties, as shown by its loss of the

power to crystallize and also by the loss of its power to produce the reaction

This protein, apparently, is not free from the bacilli except when they disintegrate or are autolyzed. It is, therefore, an endotoxin, as is that derived from the typhoid bacilli, but unlike the diphtheria toxin which is normally secreted into the culture medium by the diphtheria bacilli. As the reactive substance derived from the tubercle bacilli is a protein, Dr Herbert regards the reaction given by it as an allergic one. If it is so, then it is difficult to explain why the reaction occurs, for tubercle bacilli must, in tuberculous animals, undergo autolysis and the protein set free should continuously give the reaction. Is this protein, which is highly toxic, denatured, once the early stage of infection is passed, by the clasmatoocytes which ingest and destroy the bacilli and thus prevent the protein from passing out from the tubercles? If the protein is constantly set free from the bacilli in the infected subject in more than infinitesimally minute quantities, why should the injection of minute portions of it bring about the typical reaction? These questions indicate that the exact nature of the reaction has still to be determined.

Of equal importance and interest are the results so far derived from the attack on the chemistry of the tubercle bacillus and on its constituents now being carried on under the auspices of the Committee on Medical Research of the United States National Tuberculosis Association. This Committee has secured the services of a number of specially qualified chemists, biologists and pathologists, who have arranged to co-operate in this attack. The extent of this organization may be inferred from the fact that three United States government divisions, eight universities, four endowed laboratories, two manufacturing chemical plants, seven volunteer health bodies, and two semi-governmental bodies are concerned in it. This research has been carried on for about two years, and, of course, has not as yet covered the whole of the field, but so far it has made very considerable progress. A

very brief summary of the results already obtained has been recently furnished by Dr W. C. White*, of the United States Public Health Service, Washington, who is engaged in co-ordinating the work of the group of workers.

A number of the unaltered constituents of the bacilli, cultivated for six weeks in the Long synthetic medium, have been isolated by Professor Treat B. Johnson, of Yale, and distributed amongst the other workers who are engaged in ascertaining their action on normal animals. These constituents are a nucleo-protein, several proteins, a polysaccharide, sulphur-containing compounds and a phosphatide fraction. The effects of injections of the proteins and of the phosphatide have been studied by Sabin and Doan of the Rockefeller Institute. The protein fractions gave markedly toxic effects, high fever, multiple hæmorrhages, and a very great increase in the number of clasmatoocytes, especially in the so-called interstitial pneumonia of the lungs. The significance of this increase in the clasmatoocytes is found in their activity in ingesting and fragmenting tubercle bacilli. The phosphatide fraction, which is entirely non-toxic, gave, on injection into the peritoneal cavity, massive local increases in the monocytes, epithelioid cells and giant cells of the Langhans type, which are special constituents of typical tuberculous tissue, and which "house" as it were the tubercle bacilli in the chronic infections. This property of the phosphatide fraction has later been shown, after a finer fractionation, to be due to a *saturated fatty acid*. What this fatty acid is has not been determined, but it must be of a kind hitherto unknown.

From all this it is evident that very great advances have been made in our knowledge of the chemistry of tuberculin and of the tubercle bacillus, and it is not too much to hope that in the next few years we shall be in a position to combat tuberculosis fundamentally and effectively.

A. B. MACCALLUM

**Science*, July 13, 1925

the mistake of trying to apply it at the wrong end, that is, on this side of the Atlantic

The results of compulsory examination had been seen before the system was adopted for all immigrants, as the plan had been in operation in the case of unaccompanied women, children's immigration schemes, and government-assisted passages to Canada, and it was found that striking results were obtained from it. In 1926, the last complete period for which figures are available, about 95,000 immigrants arrived in Canada without compulsory examination before embarkation, and the medical inspection at the ports of entry (never adequate for the detection of certain types of disease or disability) eliminated only 0.03 per cent of mental defectives, and 0.04 per cent under the head of chronic loathsome diseases. On the other hand, of 20,000 of the assisted immigrant class who underwent compulsory medical examination before embarkation, 0.75 per cent of them were declined as mental defectives, and 0.97 per cent as suffering from loathsome disease were weeded out and refused admission.

The new scheme of examination called for the appointment of Canadian medical inspectors at the various centres of embarkation, and the plan was only put into force after much consultation with officers of the British Medical Association, the British Ministry of Health, and the steamship companies. Nevertheless strong criticism soon appeared in the public press, based professedly on the ground that the proposed examination would act as a deterrent to immigration. Dr. Pagé states that the opposition was traced to certain of the shipping interests, and he holds, and rightly, that the criticism at such an early stage of the work was unfair. It is true that there

was a decrease in immigration to Canada of 12 per cent in the first three months of 1928 compared with the same period in 1927, but this fact loses its ominous aspect when it is found that in the same period the immigration from the British Isles to Australia, New Zealand and the United States showed an even greater comparative decline. No such opposition, it is added, arose when the United States adopted a similar scheme some years ago. Dr. Pagé looks forward to a steady improvement in the working of the plan. It is an encouraging sign, rather than otherwise, that even in the short time for which figures are available, there has been a decided increase in the number of those rejected as unfit.

Coupled with Dr. Pagé's stimulating account, we would call attention to the effort being made by the Canadian National Committee for Mental Hygiene towards the study of mental hygiene problems presented by incoming settlers in the West. If, as has been pointed out¹, our new Canadians are contributing more than a fair proportion of the population of our mental hospitals, our jails, and our charitable institutions "it is important that we should know the reasons." To this end, information should be collected regarding the various racial groups who come to us from other lands, about their health, their educability, their national ideals, etc.

The importance of, and, we may add, the difficulties connected with, such work, are hard to over-estimate. It will, however, provide evidence of the value of the application of medical science to the problems which beset the growth of our people.

THE QUESTIONABLE BENEFITS OF THE VOLSTEAD ACT

DOUBT appears to exist among members of the profession in the United States as to how far prohibition is furthering the welfare of the people. In a recent address before the Academy of Medicine¹ Dr. Charles Norris, Chief Medical Examiner in New York City, asks the question "Has prohibition been worth while?" Statistics at present,

according to him, would indicate that the Volstead Act has not had the beneficial action claimed for it, and that "speakeasies" in increased numbers have taken the place of the corner saloons in New York City. The supporters of the Act make statements in the newspapers that it is pleasant to contemplate the way in which the corner

saloons have been replaced by flower stores and groceries, but nobody knows how many of these flower stores and groceries have back rooms where liquor is obtainable. Many, also, who want to drink wine or spirits have become potential manufacturers. Prohibition, according to the speaker, has not only increased the amount of drinking, but has also increased the risks attendant upon drinking by supplying impure alcohol. The enforcement of the Act has cost the nation nearly 178 million dollars, while in the way of revenue the nation loses approximately a billion dollars a year. Statistics obtained from the Hospital Information Service Bureau of the United States Hospital Fund show that prohibition has not stopped the ambulance calls for cases of delirium tremens, 472 cases of which were last year removed to hospitals, and 8,102 cases of acute alcoholism were treated in the hospitals. Dr. E. Monin, in his volume on "L'Alcoolisme," a medico-social study published in Paris in 1917, makes the statement that while abstinence is ideal, the public should not demand anything but temperance. Temperance alone can create a superior and anti-alcoholic class. For the public the use of alcoholic drinks must be a question of moderation.

Another aspect of prohibition has been dealt with by Dr. Louis I. Dublin, of the Metropolitan Life Insurance Company, in a paper² published in full in the *American Journal of Public Health*, January, 1928. In this article Dr. Dublin states that the prohibition period has been characterized by sharply declining mortality rates among children and adolescents of both sexes. The improvement becomes smaller among young male adults and disappears altogether in the middle years of life in that sex. Among men the mortality rate definitely rises after the age of thirty-five. In a general way, it may be said that over half of the total population has experienced a very favourable morbidity and mortality rate during recent years. One may even go a bit farther and say that the facts are consistent with an assumption that the conditions of life during the period of the new legislation have been beneficial to a large part of the public. A little arithmetic will show that there has been a saving each year of about 14,500

children under the age of five of another 2,000 between the ages of 5 and 10, and another 1,000 between the ages of 10 and 20. This makes approximately 17,500 young lives saved in a year. At the age of childhood the greatest improvement in the death rate has taken place in connection with accidents, diarrhoeal diseases, and pneumonia. Infectious diseases have declined considerably. Among young women there has been traceable a decline in tuberculosis. There has also been a sharp decrease in mortality from puerperal causes. It would appear, therefore, that the improvement during these years is a response in some measure to the direct attack going on for years by health and social service agencies, both public and private, against the communicable diseases and against the diarrhoeal diseases of children, and may be considered a reaction to a rising standard of living. The conditions of domestic life, during the last few years, have apparently been such as to add incentive and power to the forces already at work to make for better health and longer life in these classes of the population.

While emphasizing this improvement in economic conditions Dr. Dublin is not willing to accept without qualification the suggestion that that part of the wages that under the old régime went into the liquor traffic is now diverted into channels which afford increased protection and welfare for the family. This phase of the subject is unfortunately beclouded with much uncertainty, and we know very little that can be considered as accurate with reference to the amount of alcohol now being consumed, of what is being spent for it, and, least of all, how the facts affect the various economic levels of the population. Under the heading of "An increase in male deaths due to alcoholism" he makes the statement that the improvement in tuberculosis has gone hand in hand with an increase in the mortality from pneumonia, from accidents, from heart disease and kidney disease. Since the year 1920 there has been a constant rise in the death rate from alcoholism and from cirrhosis of the liver. The picture we now find to exist in the mortality rate of adult men in the United States is entirely consistent with the observations universally confirmed of a continued widespread indulgence in alcoholic

beverages by men. The quality of liquor used throughout the country is sufficiently bad to make up for the smaller quantity consumed. There can be little question as to the unsatisfactory situation now confronting large areas of the country as regards the use of alcohol by men. Beginning with 1920 there has been a continuous and marked rise in the number of deaths resulting from the use of alcohol. The situation is in striking contrast with what has occurred in neighbouring Canada. The experience of the Metropolitan Life Insurance Company in Canada is especially instructive. Among over one million policy holders there have been recorded only one hundred deaths from alcoholism and acute alcoholic poisoning during the entire period 1911 to 1926 and on the annual basis the number of deaths from these causes is so small as to be almost negligible.

An editorial in a recent number of the *Journal of the American Medical Association*³ remarks that economists, sociologists, and physicians alike seem unable to evaluate the success of the present law relating to the consumption of alcoholic beverages. While some seem inclined more in its favour, others are rather against it, and statisticians in general are agreed that reliable facts on which to form judgment are not available. One cannot read the recent discussion of a group of eminent British psychiatrists on the etiology of alcoholism without realizing that the very nature of this social and personal demand for drink is yet to be determined. Can the craving precede indulgence or does it arise therefrom? One speaker suggested that the drinking of alcohol in excess results in the production of chemical compounds which produce a form of nervous distress that only more alcohol can relieve. Another authority equally reputable scoffs at this idea and declares that he has never been able to satisfy himself that there is any value in the treatment by alcohol of the early stages of delirium tremens. Another asserts that men do not drink until after they have made the discovery of the euphoria that results from this experience. It is, however, not by any means agreed that the desire for pleasure is the stimulus that urges men to drink. The more orthodox view as expounded by a

committee of the Medical Research Council is that the direct effect of alcohol upon the nervous system is in all stages and upon all parts of the system to depress or suspend its functions, in short, from first to last alcohol is a narcotic drug. That this generally recognized view has some distinguished opponents only serves to illustrate the lack of certain knowledge. The relatively high incidence of alcoholism in the United States cannot be explained on the theory that chronic drunkenness is invariably the consequence of a desire to escape misery. The conviction is forced upon us that these yet unsolved problems are not insoluble, they constitute a definite challenge to research.

With the object of obtaining more effective control over the prescribing and dispensing of liquor for medicinal purposes, the Commissioner of Prohibition in the United States has promulgated a series of new regulations which became effective last August. The new regulations relieve pharmacists of the necessity of making copies and keeping exact records of the prescriptions containing liquor that they are required to dispense, copies of which they were previously required to file monthly with the prohibition administrators. Under the new regulations only a brief record of the prescription is demanded. The chief labour of recording is now placed on physicians prescribing liquor, as they are required to write four copies of their prescriptions instead of two, and make monthly reports to the Commissioner of Internal Revenue instead of reporting only when their book of prescription blanks was exhausted. Although physicians are relieved of the statutory duty of returning to the Commissioner the book of stubs of used prescriptions, this concession would appear to be of little value as it is expected that the directions which the Commissioner will lay down will be no less elaborate than the formula now prescribed. According to an editorial in the *Journal of the American Medical Association*⁴ physicians will have to make their monthly return to prohibition administrators by registered mail with requests for return receipts, so that the annual outlay by the medical profession for postage and registered fees will amount to approximately \$180,000.00 a year. The *Journal* adds that the new regulations will increase the expense of the medical pro-

fession by about a quarter of a million dollars annually, and this item of cost will enter into the general expense of medical practice to be passed along and become an additional charge on the sick

CRITICISM OF CALMETTE'S STATISTICS ON THE EFFICACY OF BACILLUS-CALMETTE GUÉRIN VACCINATION

IN previous editorials in this journal the subject of vaccination of children against tuberculosis by the use of B C G, an avirulent living tubercle bacillus, has been discussed

A recent editorial in the *British Medical Journal* by Greenwood¹ has severely attacked the validity of the statistical study of the results in vaccinated children, which it must be remembered is one of the factors Calmette has employed to stress the value of his method of vaccination. Greenwood's article is a masterpiece of poignancy, telling sarcasm, and pointedness, and is well worth reading. In brief, he shows conclusively that Calmette has misquoted the literature he cites on the mortality rate from tuberculosis in non-vaccinated children exposed to contagion, these erroneous figures being used as controls with which to compare the figures obtained in his vaccinated children. Furthermore, he demonstrates that Calmette has mishandled his own figures as Greenwood succinctly puts it, "he has introduced a novel method into statistics." When one bears

in mind that Greenwood is Professor of Epidemiology and Vital Statistics in the University of London his editorial must convey much weight. If further evidence were necessary it is supplied by Rosenfeld² in Germany, who has independently arrived at similar conclusions, and has also pointed out other statistical errors made by Calmette. One of the main props in Calmette's edifice, *i e*, his statistical studies in vaccinated children has thus been proved unsound. Another prop, his experimental results in animals, has been criticized by Petroff³, who advises extensive experimentation in cattle as a necessary preliminary confirmation.

Certainly the use of this method of vaccination of infants against tuberculosis in Canada appears to be premature at this juncture.

THE CREATINE PHOSPHORIC ACID OF MUSCLE

MUSCLE contains 0.3 to 0.5 per cent of creatine, and ninety-eight per cent of all the creatine in the body. Creatine is a fairly soluble compound, liberated very readily from minced muscle. What its function in muscle is, and even how muscle holds it and prevents its passage into the circulation, have long been puzzles. Some clues to these have recently been discovered.

Last year Eggleton and Eggleton¹ reported the presence in muscle of an unstable compound of phosphoric acid, which disappears completely when muscle enters into

rigor. They termed it *phosphagen*. Fiske and Subbarow² simultaneously found similar results, but went further and isolated phosphagen, showing that it was a creatine phosphoric acid, in which a nitrogen atom of creatine is linked directly to the phosphorus atom of the acid, a type of combination not previously found in biochemical compounds. The work has been rapidly extended by Meyerhof and his school³. They have shown that there are two "phosphagens." While vertebrate muscle contains creatine, its place in invertebrate muscle is taken by the

amino-acid arginine, closely related to it chemically. This muscle-arginine is held in exactly the same kind of phosphoric acid combination.

When muscle is rapidly fatigued the complex creatine compound is largely decomposed. Either in presence or absence of oxygen it is rapidly reformed. These changes are brought about by a specific muscle enzyme. Whether decomposition or synthesis takes place depends respectively upon whether the muscle-medium is slightly acid or slightly alkaline. Since muscular contraction at once tends to produce slight acidity through the production of lactic acid, as a result of muscular contraction free creatine is liberated. The balance of evidence favours the association of muscular work with the production of creatinine (subsequently excreted in urine) from creatine, and we know that this change takes place automatically in acid solution. Evidently the creatine phosphoric acid of muscle is constantly being decomposed and resynthesized, and the conclusion is unavoidable that these changes are functionally linked up with and functionally necessary to the carbohydrate metabolism of muscle whereby this

tissue carries on its specific function. It seems not improbable that the formation of creatinine represents the unavoidable and incidental loss of creatine from muscle involved in the frequent production of an acid medium during muscular work. Such type of loss of compounds that the body conserves as far as possible is exemplified by the constant loss of a small amount of bile acids during their passage through, and reabsorption from, the intestine. It still follows that the creatinine output in urine affords an index of muscular work and the muscularity of the individual.

Although these discoveries are so recent, they are so definite in character and have such potentialities that in the near future we may expect to obtain a much clearer insight into the whole mechanism of muscular metabolism.

FOOD PIGMENTS

THE most obvious and least considered property of food, taken as a whole, is its colour. The purple, red, yellow and orange colours of fruits have been regarded as appealing to the eye and to our sense of beauty only but as having little or no food value. Efforts have recently been made by chemists to estimate the physiological significance of those food pigments that were shown to be chemical entities, but until recently hæmoglobin was the only pigmented substance in food regarded as having a definite food value. Recent investigation would indicate that carotin must also be placed as an article of diet possessing a definite influence on nutrition.

In addition to the green chlorophyll two other pigments, xanthophyll and carotin are known to be present in vegetables and fruits. Both of these are yellow substances, obtainable in crystalline form, and can be

demonstrated in corn, carrots, and sweet potato. Carotin is a hydrocarbon, while xanthophyll contains oxygen in addition to hydrogen and carbon. These pigments are always found together, although in varying proportions, and it has been shown that the carotin of milk fat, blood serum, and the adipose tissue of cattle is derived from the carotin-bearing foods which they eat. Xanthophyll, which predominates in egg yolk, is also dependent on the special food given to the fowl. While there appears to be a striking parallelism between the occurrence of vitamin A and these yellow pigments, careful studies have shown that neither xanthophyll nor carotin can replace this fat soluble vitamin in the diet. In experiments which have recently been carried out by Underhill and Mendel¹ on dogs, it was found that definite indications of malnutrition characterized by lesions in the mouth and in

the gastro-intestinal tract developed in dogs fed on a restricted ration, and that this malnutrition could be prevented and cured by feeding food containing carotin in minute amount. The results indicated a remarkable potency of this pigment for as little as five milligrammes of crystallized carotin fed daily was efficacious in removing the indications of malnutrition.

Experiments of a somewhat different character were carried out by Connor in Harvard². A solution of carotin in olive oil was injected intraperitoneally with the result that at the necropsy a month later granulomatous lesions were found in the mesentery, on the spleen,

and on the liver. A control animal injected with olive oil showed none of these reactions. These results would indicate a considerable potency of this pigment. It is suggested that carotin taken with the food may be so altered in the course of digestion as to provide a physiological essential to the organism, but when given intraperitoneally it may only act as a foreign body.

Editorial Comments

DEATH OF LADY OSLER

News of the recent sudden death of Lady Osler, the devoted wife of the great physician Sir William Osler, has come with a painful shock to the thousands of friends and acquaintances who glimpsed the happiness and were admitted to the intimacy of the Osler's delightful home at Baltimore and later of "The Open Arms" at Oxford, during their twenty-seven years of married life. So warm and gracious was the overflowing hospitality there accorded, and so freely was this extended to all who came within its range, that a day, or even an hour, spent within its radiance stands out in the memory of all who were so privileged as a bright and sweet experience, alive with vivid human interest, the enkindling influence of which is with us still. In this truly unique side of Sir William Osler's life and activities lay perhaps his greatest gift to his generation, for though it there was diffused, as by an electric current, and in an ever-widening radius, that spirit of universal fellowship, which, even amid the turmoil of the great War, was yet the very air in which his spirit breathed.

In the exercise of this extraordinarily broad and generous hospitality in which it was ever his impulse to indulge, Sir William Osler was not only ably seconded but was carried forward to achievements beyond anything he could have encompassed alone by the magnificent organizing power and social genius of Lady Osler, whose intuitive support of his every wish and interest and warm sympathy for all about her bridged the shyness of the most timid guest, and met the complexities of the most apparently trying situation with complete ease and invariable success. From their early years in Baltimore, when the "dear Mrs. Chief" shared the student evenings

round the dining table, or carried on serenely at the tea hour with Dr. Osler's guests long after he had slipped away from them, down to the crowded days of the great War, when at 13 Norham Gardens open house was kept for practically all the American and Canadian officers who passed through England, Lady Osler was equal to every emergency. And, when the hour of trial came, bereft of their dearly loved son, "to her" (to quote Dr. Malloch's words*), "sorrowing too, but standing upright at his side, he turned for comfort and support, and she, who had been his stay and helpmate in all his work, gave him power to bear it to the end."

Perhaps, if that dreadful time of immense pressure and strain had not supervened, the integral share which Lady Osler had in the supreme consummation of Osler's life and powers would not have been so apparent to us all. In such relations the half has never yet been told nor known, and the part which such a wife with powers consecrate takes in the successful fruition of a great man's work is to be read only in the completeness of his fulfilment. Lady Osler's best epitaph lies in the universal love and reverence in which Sir William Osler's name is held throughout the world of modern medicine. Nor would she ask a greater tribute than this recognition of her own unselfish work.

Lady Osler's activities did not cease with Sir William's death. She was elected then a trustee of Ewelme Almshouse (the only woman who has ever had that honour) and to the Board of Radcliffe Infirmary and as Sir Herbert Warren writes in the *London Times* of September 4, 1928,

* Archibald Malloch "Sir William Osler at Oxford." *Sir William Osler Memorial Volume* 1926 p. 77.

"She did indeed a noble work after her two great sorrows, from which she never really recovered, by keeping open her hospitable home as an international centre, a house of call with an ever-ready welcome for so many a passing traveller, and for the constant, often almost daily, reception during term of the young students of her own country and their friends, to whom it was truly a liberal education to be admitted within its walls, a living link between the United States and the British Empire—between Old and New England."

Lady Osler (Grace Linzee Revere) was born on June 19, 1854, the daughter of John Revere and of Susan Tilden Revere, both of Boston, and was thus the great grand-daughter of Paul Revere* of American Revolutionary fame. She was married, December 28, 1876, to Dr S W Gross of Philadelphia. Three years after his decease, she was again married, on May 7, 1892, to Dr William Osler, then of Baltimore, who pre-deceased her on December 29, 1919. On December 23, 1927, she had a slight stroke, which left her with a paresis of the left side of the body and in a somewhat depressed condition. During the ten days before her death she had been rather brighter than usual, seeing many old friends who were passing through Oxford, but on the morning of August 31st, she became suddenly unconscious with signs of the onset of a left hemiplegia, and died quietly without any pain, and with only momentary discomfort, at her home at 13 Norham Gardens in the presence of her sister Mrs Chapin and Dr John Fulton of Boston. Her passing closes a chapter dear to the hearts of many, whose thoughts follow her with profound affection, and with an ever deepening admiration of a simple, unselfish, heroic spirit that counted not the cost, and herself as but worthy to "do what she could."

Lady Osler is survived by her sister Mrs H B Chapin of Jamaica Plain, Mass, and by three brothers, Mr "Joe" Revere (formerly of Sydney, Cape Breton), and Messrs William and Edward Revere, all now resident at the old Revere homestead at Canton, Mass.

MAUDE E ABBOTT

An Appreciation from an English Source

"Grace Revere, Lady Osler, born 74 years ago

* Paul Revere was of French descent, and the name was originally *Appolos Revoir*. "I was with Lady Osler and Mrs Chapin in Vienne Cathedral some years ago," writes Mrs H P Wright of Montreal, "when they found there the coat of arms of Appolos Revoir. A branch of the family moved to one of the Channel Islands, and a descendant came out to the United States and changed his name to 'Paul Revere' for convenience sake, rather offending his relatives in the Old Country by so doing."

at Boston, was the great-granddaughter of Paul Revere, the hero of the famous ride. As a young woman she married Dr S W Gross, a professor of the Jefferson Medical College, Philadelphia, and the son of Samuel Gross, the famous American surgeon. She was left a young widow in 1888, and three years later married William Osler, who, having come south from Canada, was making his famous reputation as a scientist and physician at Baltimore. For thirteen years Lady Osler was her husband's helpmate at Baltimore, then, in 1905, came the appointment to the Oxford chair, and from the moment that Osler and his wife arrived in the old University city it was seen how admirably they were fitted for what they made into a joint effort. A well known Oxford professor writes of her: "She was an instant success and their home became a centre of attraction, drawing all sorts and conditions of men from every quarter of the globe, the most gifted and famous mingling with the youngest under-graduates arriving to present letters of introduction. Her house was converted into a veritable home for many of the Rhodes scholars, and not a few of these will remember with affection and respect the care she bestowed upon them, her valuable influence and her practical help—things which greatly assisted in promoting the success of Cecil Rhodes's scheme." The outbreak of war found Lady Osler in America, but she returned immediately and threw herself whole-heartedly into all the activities connected with the succour and treatment of the wounded, while owing to her influence in America, she was from the beginning able to obtain great sums of money to carry on various schemes. As is well known her only son was killed at St Julien but stricken as she was, she only bestowed herself to help with more intimate and perfect sympathy those who could not help themselves. She was an ideal companion to her husband. Trueless as she had been in promoting the interests which he had at his heart, it was felt by everyone that her appointment at Sir William Osler's death as Trustee of the Ewelme Charity was thoroughly fitting, the Mastership of Ewelme in connection with the Chair of Physics had been a medieval appointment which had made a special appeal to Sir William Osler."—(*The Lancet*, 1928, ii, 513)

STRENGTHENING THE BONDS OF BROTHERHOOD

In a recent issue of the *British Medical Journal* (1928, ii, 121) appears an article by Mr Victor Bonney, who therein gives a most interesting and thought-compelling account of his visit to New Zealand and Australia, where he went as the official delegate of the British Medical Association to the conference of the New Zealand branch. The issues that he raises are important enough to call forth editorial comment

in the same magazine, and are well worth attention also in this part of the Empire

Mr Bonney waves enthusiastic over the attractions which Australasia has to offer the visitor, and speaks also in high praise of the hospitals and medical schools of the island continent and its neighbouring Dominion. Of New Zealand, in particular, he says, "The most beautiful and varied scenery of mountain, lake, forest, and river, with volcanic phenomena which are of great interest without danger, and with a temperate climate comparable with our own but more sunny—all these and more will well repay a visit, to say nothing of the warm welcome which the medical tourist may safely count upon from our professional brethren overseas"

Mr Bonney expresses the fear that, inasmuch as Australia and New Zealand are much nearer in distance to the United States than they are to Great Britain, and America can in some sense be regarded as the half-way house between the Antipodes and Great Britain, there may be some danger that the spiritual home of Australasia may some day be transferred from Europe to America. On this point the editorial referred to goes on to say "It must be admitted by all of us that such a transfer would be regrettable, for the people of Australia and New Zealand are of almost pure British inheritance, while the population of the United States has for some time ceased to be pre-dominantly British in blood. More and more, in all probability, will the Southern European elements in the United States assert themselves in future generations, despite the present regulation of immigration by means of quotas." To maintain, not to say, strengthen, the bonds of brotherhood in this far-flung Empire of ours is no light task, but it can and should be done. It is true that science knows no bounds, and the domain of letters has been termed a republic, yet the experience of the Great War has shown that in the last analysis the ties of blood are strongest. This fact should fill us with hope. Let us unite to maintain the British tradition in medicine. The British Medical Association, mindful of this duty, has at various times sent delegates to Australasia, South Africa, and Canada, with the avowed intention of maintaining contact and strengthening and multiplying the bonds between the profession in the centre of the Empire and that in the overseas Dominions. The results have been excellent. The visit of Dr Alfred Cox to Canada, for example, did much to bring about the affiliation between the Canadian and British Medical Associations, a bond that will be strengthened by the Annual Meeting at Winnipeg in 1930.

This, however, is not enough. The *British Medical Journal* is of the opinion that, in addition to the "personal touch", steps should be taken to improve the facilities for post-graduate teaching in Britain, so that the calls of other

countries would be less seductive. It goes on to say "The most crying professional need in this country is for a post graduate hospital and school whither not only visitors from overseas, but our own graduates, could resort for the higher medical education. In New York there is a large and well-equipped post-graduate hospital, and the Johns Hopkins Hospital in Baltimore, of world-wide fame, also offers openings to graduates. Here in London the Fellowship of Medicine is worthy of support as a co-ordinating body, but its scope is too limited at present." We would express the hope that something be done speedily to implement this suggestion.

May we hazard a suggestion? It is that a very special, even urgent, invitation be extended to our confrères in Australia, New Zealand, South Africa, and Newfoundland to visit Winnipeg in 1930 and that some of their outstanding men be asked to deliver their proportionate share of the principal addresses. They will be very welcome in Canada. Members of our Canadian profession made many friends among Australians and New Zealanders during the War and on different occasions since visits official and unofficial have been made to us by men from the Lands of the Southern Cross, to our great delight and improvement.

Let Canada on the occasion of the British Medical Association meeting two years hence figure as the "half-way house" and be the common meeting ground of Britons from the Home Land and the Dominions overseas. A C N

THE TOUR OF THE TUBERCULOSIS SPECIALISTS

It is with much pleasure that the *Journal* desires to acknowledge on behalf of the Canadian profession the generosity of the Sun Life Assurance Company of Canada in sending thirty-five of the officers of our various Tuberculosis Institutes on a travel tour to last over seventy days, and in making full arrangements for their attendance on the special conferences on tuberculosis which are taking place in several European countries as also for their inspection of the more important anti-tuberculosis institutes in England and on the continent. These officers comprise the directors and superintendents of all our tuberculosis sanatoria throughout the Dominion and include representatives from every province. The conferences which on this trip they will be able to attend in Rome, London, and Paris cannot fail to be of much educational value and should be of great advantage to them in their efforts against tuberculosis in Canada.

In sending this group of physicians over the Sun Life Association has been most generous—not only in permitting many in the party to take their wives and even their children with them but in so arranging the itinerary as to permit

intervals of rest from their professional work, and affording time to allow the party to visit many places in England and Scotland famous for natural scenery and historical association.

The *Journal* is also pleased to state that arrangements have been made with the President of the Canadian Association, Dr Jabez Elliott, to keep the readers of the *Journal* informed of all matters of general interest that may occur on the trip. On the outward voyage Dr D. A. Stewart, of Ninette, has promised to report the daily conferences on the program for the voyage. All papers of interest which may be presented at both the International meeting in Rome and at the National British meeting, which is to take place in London in October, will also be reported. We hope in this way to be able to present our readers with a full account of this unique trip, for which not only the members who are actually enjoying it but the profession generally, who will we hope reap its after fruits, have to thank the Sun Life Assurance Company. A.D.B.

THE DETECTION OF SCARLET FEVER CARRIERS BY THE COMPLEMENT FIXATION TEST

In this number of the *Journal* appears (p. 431) a valuable paper by Dr F. Green on the subject of complement fixation in scarlet fever and its importance in detecting carriers. His work was done in the laboratory of the Shriners' Hospital, Montreal, on cases both in the acute and convalescent stages of scarlet fever occurring in that institution and at the Alexandria Hospital for Infectious Diseases.

His article begins with a useful retrospect of the work done in connection with complement fixation in scarlatina, erysipelas and puerperal septicæmia, and he then details his own observations.

His series of forty cases is, of course, small, but so far as they go his investigations tend to prove that the complement fixation may be helpful in diagnosis and in the determination of atypical cases and, in his opinion also, appear to confirm the idea that *S. hæmolyticus* is the causative agent in scarlet fever.

Particularly important is his observation that a person who had suffered at intervals from sore throat, but who had never had clinical scarlet fever, gave a strong positive complement fixation test with *S. hæmolyticus*.

It was concluded that this person, an attendant in the Shriners' Hospital, was a "carrier", and this view was strengthened by the fact that as soon as she was removed further cases of scarlet fever failed to develop. So far as we are informed, this is the first time that the complement fixation test has been applied to the detection of "carriers" of scarlet fever. Dr Mackenzie Forbes' suggestion and Dr Green's care-

ful investigation of it are well worth attention. The observation, a single one, should undoubtedly be followed up, to determine more fully the value and applicability of the test for this particular purpose. Dr Green has initiated a promising piece of work. A.G.N.

STUDIES ON THE FUNCTION OF THE KIDNEYS

Some recent researches by Drs Stehle and Bourne of McGill University,* into the effects of morphine and ether on the function of the kidneys, serve to show how incomplete our knowledge still is regarding the many problems involved in the production of urine. These investigators point out that it has long been known that anaesthesia diminishes the volume of urine, and that there are data concerning the effects of anaesthetics on metabolism in general, as represented by the urine, but apparently no study has as yet been made of the effects of anaesthesia on the function of the kidneys.

They have therefore carried out a series of experiments on dogs with ether and morphine, using these drugs both separately and together, but are unable to interpret their findings on the basis of the modern filtration-reabsorption theory of urinary secretion. The action of ether, they show, is definitely to lower not only the quantity of urine, but to decrease the concentration of the urea and chlorides. It is well-known that ether causes a concentration of the blood (apparently because of the passage of plasma into the tissues), it might be expected therefore that owing to this the kidney tubules would absorb more water than usual, and so leave a relatively high concentration of urea and chlorides. But this does not happen, and it is obvious that opposed to the theory of ordinary filtration some secretory mechanism is concerned whose action is impaired by the ether.

The effects of morphine on the secretion of urine were shown by these workers to be, in general, the same as those of ether, though in less degree. When, however, the two drugs were employed in combination the surprising observation was made that the secretion of urine was decidedly less interfered with than when ether alone was given. It is suggested that a likely explanation of this is that owing to the previous administration of morphine less ether is actually used, since etherization is always more easily produced after morphine narcosis.

The paper should be consulted for full details of an inquiry which is an excellent example of the testing of physiological theories by their application to problems of clinical interest.

ANNUAL MEETING OF THE CANADIAN COUNCIL ON CHILD WELFARE

The ninth annual meeting of the Canadian Council on Child Welfare will be held in Ottawa, October 22nd. The executive meeting will take place at 9 a.m. The general meeting will be convened at ten o'clock and continue all day, with a short recess at noon, and terminate with an informal dinner at 7 o'clock. The President will open the business meeting with an address which will be followed by reports from the various office bearers and the reports of the several provincial sections. Among the important subjects to be discussed will be a revision of the constitution. The alternative changes now suggested will fundamentally affect the Council's organization and work, and every member is earnestly requested to study the proposed changes which have been circulated to all the members. Juvenile immigration findings will occupy entirely one session, and it is hoped that the Dominion Department of Immigration will assemble at the same time the several provincial child welfare directors and the heads of the British Juvenile Immigration society for a closed conference.

In addition to these matters, staff conferences and financial policies will come up for discussion, and will likely make this the most important annual meeting since the Council's establishment. A special effort to attend this important annual meeting is urged upon all the members.

A.D.B.

BRANDON MENTAL HOSPITAL

Report of the Royal Commission

The *Journal* is pleased to give prominence to the following item, taken from the *Manitoba Medical Bulletin*, which is self-explanatory, and to offer its congratulations to Dr. Baragar, who

has so triumphantly emerged from a very trying experience.

The Royal Commission appointed to investigate the charges laid by William Ivins, M.L.A., against Dr. C. A. Baragar, Superintendent of the Brandon Mental Hospital, has recently presented a report signed by the three members of the Commission, Judge Barrett, of Carleton Place, Mr. A. W. Puttee and Mr. Thos. Sharpe of Winnipeg. The report of the commissioners was expected by all his medical colleagues as a complete vindication of Dr. Baragar. The unanimous finding of the Royal Commission is that Dr. Baragar has done a splendid piece of work in re-organizing the hospital, that he has left nothing undone to bring the hospital to a plane where the treatment and the handling of the delicate and complicated task of caring for a thousand mental patients is a credit to an enlightened community and that nothing exists to justify the slightest suspicion that the Brandon hospital and the staff are not fulfilling their duty toward their patients in a sympathetic and enlightened manner.

"Thus the charges laid on the floor of the Legislature have completely collapsed. It is unfortunate, however, that the province has to bear the expense of a Royal Commission to investigate charges which were proved to be practically baseless and that a public servant of the character and attainments of Dr. Baragar should have been placed on trial. In a fine editorial the *Free Press* says: 'The public is assured that the Brandon Mental Hospital is above reproach and that in Dr. Baragar it has a superintendent who has given himself without stint to the service of the people in handling a task from which many would recoil. It is fortunate for the people that the state is able to attach this type of citizen to the public service.'"

Extra doses of ultra violet light are not so good for plants as for animals, it appears from experiments carried on in London by E. M. Delf, K. Ritson and A. Westbrook, working at Kew Gardens and Bedford College. The experiments were undertaken with the idea of finding the possible effect of the light on plants brought from the south to northern countries where there is much less sunshine. Seedlings and older plants were given treatments with quartz mercury vapour lamp, similar to those given human beings. Germination and growth were retarded and in older plants leaf formation was partially inhibited and flower formation and bud development were held back.—*Science*, June 20, 1928.

Health Supervision of Executives in Industry—

Halsted G. Murray points out that health supervision in industry must have the approval and support of the directors of the concern. The examinations should preferably be on a voluntary basis and done if possible, at

the factory on factory time. From experience it is like the health examination, give their cooperation. The advice given in regard to living habits and rules of health and correct a large percentage of minor physical defects. Most business men have no exercise during the winter. An indirect result of examinations is that facilities for exercise are provided on company time. Men who travel are protected against smallpox and typhoid. As a result the number of colds has not with the degree of success. Colds, naturally are the most common ailment and are responsible for the greatest amount of lost time and discomfort. Adequate rest and adjustment of hours must lead to better health and better thinking. Men returning to work after illness are seen by the factory physician first. The result is that it is felt that health supervision has done enough worthwhile results to justify its cost.—*J. Am. M. Ass.*, 1928, xc1, 627.

Special Correspondence

The London Letter

(From our own correspondent)

The outbreak of a mild epidemic of paratyphoid fever in the London area has led to a certain amount of agitation in the newspapers. Up to date more than a hundred cases have been notified and the disease appears to be of a very mild character. What has been alarming people is the suggestion that the organisms are being carried in cream, for since the beginning of the year the addition of preservatives to certain foodstuffs has been prohibited. This seems unlikely. The authorities are easily dealing with the outbreak, and tracking down the source of infection should only be a matter of time. But for certain other incidents it is probable that little notice would have been taken of this epidemic. In Newcastle-on-Tyne, however, a certain firm provided "lemonade" for its workers with the result that about seventy people were affected by a severe sickness from which, fortunately, all recovered. This was traced to the fact that the "lemonade" in question was made from tartaric acid which had dissolved the enamel on certain buckets, the enamel was found to contain antimony. A more serious occurrence was an outbreak of food poisoning among certain members of the London police force with one death. This was apparently due to the infection of ham with one of the food-poisoning-group of organisms, and the intense toxæmia and rapid onset in the police cases was in marked contrast to the slow beginning of the much milder paratyphoid infections. These different occurrences have, however, been confused and the result has been a cry that the prohibiting of preservatives should be cancelled, as if 0.4 per cent of boric acid in cream could have any effect on the paratyphoid organism.

In 1926 the Ministry of Health and the Medical Research Council appointed a Committee on Vaccination under the chairmanship of Sir Humphry Rolleston. Its report, recently issued, coincides with the occurrence of several cases of post-vaccinal encephalitis and it is therefore to the section on the risks resulting from the vaccination that most people have turned. The committee have investigated the problem of the relation of vaccinia to the liability to disease, either generally or specifically, and conclude that there is no evidence to suggest this, nor does vaccinia appear to aggravate a disease already established. With regard to encephalitis, however, the Rolleston Committee is unable to be so certain. While it acquits the vaccinia virus of being the sole cause of the disease it is unable to exonerate vaccina-

tion from playing some part in its causation.

The future of vaccination in this country is, to say the least, uncertain. The occurrence of fatal encephalitis is very alarming and the mild type of smallpox which has prevailed in this country for the last five years, with its almost negligible mortality, has led to a great disinclination among the public for adult vaccination, while the decrease in infantile vaccination continues. The committee urges that the smallest amount of virus necessary to produce immunity be ascertained and that this amount be introduced into one shallow incision in the epidermis. It is doubtful whether the very guarded terms of the report will carry much conviction to either medical men or the general public, and the further investigation of encephalitis after vaccination seems to be urgently necessary as a preliminary to any fresh legislation.

If anyone causes an offensive odour to permeate the air around his factory a sanitary inspector will call at once and deal with the case, armed with full legal powers. But a schoolboy on a motorcycle can make almost all the noise he likes outside a hospital and nothing can be done, short of murder, to stop him. The cause of noise is becoming serious and at the Cardiff meeting of the British Medical Association a resolution was moved and carried that the Association support any measures designed to suppress unnecessary noise. The *Times* has had a great amount of correspondence on the question during the last month and all city dwellers seem agreed that noise is a nuisance, while experts, such as Sir Robert Armstrong Jones, have pronounced authoritatively that the nervous system must be damaged by continual noise day and night. The remedies suggested are, however, so far not very definite or promising. The heavy motor vehicle, causing vibration as well as noise, seems most to blame along with the motor hooter. The latter it is argued might be abolished since it is often used merely as a safeguard by the dangerous driver. The heavy motor vehicle, so often heard at dead of night in the main thoroughfares of London, is a more difficult problem. Perhaps special by-pass roads will have to be constructed or else the "dormitory areas" of London, as they have been called, closed to such traffic. Whatever measures may be taken it is certain that the medical profession will give them unanimous support.

ALAN MONCRIEFF

London, September, 1928

The Edinburgh Letter

(An Edinburgh correspondent)

The Annual Report of the Laboratory of the Royal College of Physicians has just been published. This laboratory was first opened in 1889 and Sir John Batty Tuke who took an active part in initiating the scheme was the first Curator. Dr G. Sims Woodhead was Superintendent. On his resignation in 1890 Dr Noel Paton the present Professor of Physiology in Glasgow University was appointed. He was succeeded by Dr James Ritchie Professor of Pathology at Oxford University who subsequently attained to the Chair of Bacteriology in the University of Edinburgh. The present Superintendent is Lieut Col A. G. McKendrick, I.M.S. who was formerly Director of the Pasteur Institute of India at Kisumu. From a survey of these distinguished names it will be appreciated that the Laboratory has always maintained a high standard of efficiency. Sir Robert Philip the Curator comments with satisfaction on the extent and quality of the work overtaken during the past year. The Laboratory has sustained a grievous loss through the death of Dr James Walker Dawson, whose researches had gained for him a high reputation among pathologists in every country. A Fellow of the College he had been associated with the Laboratory for almost twenty years. During the year twenty-four workers had been engaged in research. Their observations relate to pathological, bacteriological, chemical, physiological and statistical problems. An investigation into the therapeutic value of trime in the treatment of tuberculosis, which the Curator started a couple of years ago, has been further prosecuted. The observations, which have been carried out, do not afford much confirmation to Takeoka's assertion that the drug is likely to be of high value in the treatment of tuberculosis. In concert with Professor Mackie, the Curator has instituted a series of experimental observations with a view to assist in the standardization of tuberculin. The Superintendent and Dr Kermack have carried to a further stage their work on the mathematical theory of contagious epidemics. The results have now been published. The Superintendent has also published a statistical examination of anti-rabic treatment in India. This was undertaken as a study of the system of statistical representation which the League of Nations will shortly apply to the statistics of anti-rabic institutes throughout the world. The report forms part of the *Festschrift* published by the Centralblatt für Bakteriologie, etc., on the occasion of the seventieth birthday of Professor Richard Pfeiffer. The importance of the alkaloid harmine, to the chemistry of which Dr Kermack and his collaborators have devoted so much study, is increasingly recognized. It is now claimed that yagaine, tele-

pathine and balisterine are identical in constitution with harmine. These drugs exert powerful physiological actions. Telepathine has been found to possess the properties of a local anæsthetic. The work of Drs Kermack and Slater on the synthesis of benzcarbolines in general has thus assumed an increased importance. Dr Kermack has been asked by the Chemotherapy Committee of the Medical Research Council to carry out further syntheses. Drs Kermack and Slater have conducted a large number of experiments which may lead to the preparation of compounds related to physostigmine with the view of ultimately synthesising that alkaloid and in addition in conjunction with Dr Lumbie they have investigated the role of dihydroxyacetone in carbohydrate metabolism. It was largely as a result of this work that Dr Lumbie was recently awarded the Lister Fellowship of the Royal College of Physicians. In particular they have attempted to ascertain whether glycogen is formed more readily in the animal body from dihydroxyacetone than from dextrose. Dr David Orr has throughout the year devoted his whole time to an investigation of the pathological changes that are found in the nervous system of animals which have received intravenous doses of bacterial emulsions. The research on pulmonary diseases in children by Dr Charles McNeil has been continued while Dr J. S. Fraser continues his important work on the pathology of deaf mutism. These are merely a few of the numerous experiments which are being conducted showing that the tradition of efficiency is being worthily maintained under the direction of Sir Robert Philip and Lieut Col McKendrick.

Sir Robert Philip has been awarded the Trudeau Medal, which is given annually for the most meritorious contribution to the knowledge of the cause, prevention and treatment of tuberculosis. Sir Robert is a past president of the Royal College of Physicians of Edinburgh, and the first occupant of the Chair of Tuberculosis in Edinburgh University. His work on tuberculosis, and especially in connection with the Royal Victoria Hospital for Consumption and Southfield Sanatorium, has gained him a wide reputation as an authority on the subject. He is at present President of the British Medical Association. If anything were necessary to enhance the honour conferred by the award of this distinction, it could be found in the associations that the name Trudeau must have for any citizen of Edinburgh. It was to that great physician that the great son of Edinburgh, Robert Louis Stevenson, went in search of health in 1887. And it was at Saranac, in the quiet of the Adirondacks, that he began the "Master of Ballantrae" and completed the inimitable "Wrong Box."

The Edinburgh Royal Hospital Sports and

Garden Party were held recently. A notable visitor was Miss Lennox. She is the oldest member of the nursing profession in Scotland. In 1856 she went out to South Africa as a nurse. In 1861 she made a second trip to South Africa with the University Mission. On proceeding up country with a party to join Bishop Mackenzie, Nurse Lennox was accompanied by Miss Livingstone. At the mouth of the Zambesi River they met the celebrated explorer Dr David Livingstone, who gave them the news of the Prince Consort's death. On returning to England, Miss Lennox joined the staff of the St Thomas' Hospital under Florence Nightingale, and was appointed sister in charge of the Accident Ward. She was one of the five nursing sisters under Mrs Debble who were sent from St Thomas' Hospital to Netley in 1868 to form the original Army Nursing Service. Part of their uniforms consisted of a short red cape, and Miss Lennox still preserves the one she wore as one of the first six army nursing sisters sixty years ago. A year ago when the Scottish National War

Memorial was opened, Miss Lennox was presented to the Prince of Wales, and later in the day, to their Majesties the King and Queen. Miss Lennox has many letters written to her by Florence Nightingale and other relics and memorials of "the lady with a lamp." Another of the original six nurses of the Army Nursing Service, Miss Strong, lives in Edinburgh, quite close to Miss Lennox. One is forced to the reflection that those early nursing sisters must have been remarkable women. Florence Nightingale lived to the age of 90 and Miss Lennox in spite of her great age, in addition to being very bright and alert, is able to read large writing without glasses and has not the slightest trace of deafness.

Dr R M M'Kenzie Johnston has intimated his resignation as a representative of Edinburgh University Comt on the Curators of Patronage, and the Court have elected Sir Norman Walker to the vacancy.

GEORGE GIBSON

23 Cluny Terrace, Edinburgh

British Medical Association

ANNUAL MEETING, CARDIFF

BY GEORGE GIBSON, M D,

The annual meeting of the British Medical Association is past and gone, leaving a memory of an interesting and instructive week that added to one's store of pleasant memories and removed certain definite misconceptions. In the minds of many, prior to the assemblage, Cardiff must have existed as a third-rate town, black with the smoke of factories and dirty with the dust of coal-pits. How different was the reality! We found in South Wales a fair capital with wonderful public buildings gleaming white under bright skies, a clean, modern, shunless city with fine open spaces and thoroughfares planted with trees.

The activities of the meeting centred around Cathays Park, which along with the Castle is the chief glory of Cardiff. Here are the Law Courts, the City Hall and the National Museum of Wales, and further north the University College and the graceful War Memorial. These public buildings are constructed in a certain uniformity of design that has resulted in a pleasing harmony, at once a successful and striking feature. Built of Portland stone, which in the clean atmosphere of Cardiff weathers to a silvery whiteness they presented a pleasing appearance to the visitors from the more grimy cities of England and Scotland. Cardiff might have been specially designed for a meeting of the Association.

The comfortable classrooms of the University College were particularly well suited for the meetings of the scientific sections while the receptions and entertainments in the City Hall and National Museum were held under most happy circumstances. In the afternoons excursions were arranged to visit scenes of interest, such as the docks and the various Welsh castles in the neighbourhood. On July 26th a garden-party was given in the grounds of Cardiff Castle by the Most Honourable the Marquis of Bute, K T, and the Marchioness of Bute, which had a special interest as it formed part of the celebrations in connection with the coming of age of their son, the Earl of Dumfries.

Sir Ewen Maclean, F R C P, the President of the Association, in his presidential address on "Some reactions and a retrospect," spoke of the "veritable pageant of advancement in the science and art of surgery." He dwelt on the growth of knowledge from the days of ancient Chinese medicine and the advance in learning in the field of medicine since the last meeting in Cardiff in 1885, emphasizing the work of the British Medical Association for the public good and pointing out with considerable care that the power and influence of the Association was not expended in the personal interest of its members, but that since its foundation the Association had been concerned chiefly with the maintenance of a high professional standard in education and conduct, the promotion of scientific research and the development of a national health policy.

In this connection Sir Ewen recalled the fact that it was the British Medical Association which first suggested long ago that a special department of Government should be created to deal with matters of public health a suggestion that finally brought about the establishment of the Ministry of Health and traced the responsibility of the creation of a School Medical Service to its recommendation. In reviewing the progress of medical knowledge and research during the forty three years since the Association last met at Cardiff the speaker alluded to the vast saving of human suffering and the prolongation of human life which were results of that progress. He referred particularly to the advance in knowledge in bacteriology, biochemistry and endocrinology and to the fact that tuberculosis, diabetes and pernicious anaemia had lost much of their former terror for humanity. While the fall in puerperal sepsis and mortality has been appreciable it has not been proportionate to that of the general nor of the infant death-rate. As a gynaecologist and obstetrician Sir Ewen Maclean's statements should carry great weight with the public and with the recently appointed Departmental Committee of the Ministry of Health. He concluded his address by suggesting that the Association should interest itself in the subject of post-graduate teaching, a problem of vital interest not only to ourselves but to members of the profession coming from overseas.

The Representative Meeting which took place before the commencement of the ordinary meeting was productive of several interesting discussions, resulting in the adoption of various important resolutions. A motion was brought forward by Dr C. D. Douglas of Fife that the Association should give full support to the *Association professionnelle internationale des Medecins*. This is an international organization comprising already thirty-three countries. Through this channel the British Medical Association could be brought in contact with the League of Nations through the International Labour Offices. This motion by Dr Douglas was carried by a considerable majority, thus reversing a decision previously carried by the Council.

The Treasurer (Mr Bishop Harman) moved approval of the Council's Annual Financial Report in which it was stated that the revenue from subscriptions owing to the increase in membership, was greater this year than last by the sum of £3,000. The *Journal* also showed an increase of £2,000 in revenue, arising from the increased value of the *British Medical Journal* as an advertising medium.

Sir Robert Bolam moved the report of the Council on the department of "Building." He described the alterations and improvements that are taking place at the Association's premises

at Tavistock Square, London, and explained the situation in relation to the Scottish House in Edinburgh. The latter has been enlarged by the acquisition of an adjoining house, in order to accommodate meetings of large societies and such gatherings as are likely to take place in the Scottish capital.

In connection with the great increase in treatment by ultra-violet rays there was an interesting exchange of opinion on the subject of the registration and supervision of untrained and unqualified persons undertaking the administration of electrical treatment. A recommendation of the Science Committee that suitable courses should be organized, and that only persons who have satisfactorily followed such a course should have their names placed on an approved roll was carried by a large majority.

A resolution suggesting the establishment of the periodical medical and dental examinations of all persons insured under the National Health Insurance Acts was favourably considered. There was a very interesting discussion on the subject of the installation of Paving Centres for advice and instruction in infant hygiene. Such centres have been set up in Chelsea and elsewhere and people who are willing to pay five guineas (\$26) per annum for each child may obtain the same sort of advice that is provided in the Infant Welfare Centres of the various local authorities. It was pointed out that infant clinics for the poor had already done a vast amount of good and that if guidance was refused to the suggested clinics they would probably still go on, and possibly on unsatisfactory lines. The clinics were intended to supply advice for healthy children, those who were found unhealthy would be sent to their family practitioners. The proposal was opposed on the grounds that the general practitioner was the responsible medical adviser, that with his intimate knowledge of the home circumstances, he was in the best position to give advice and guidance as to training and care. It was often difficult to say where treatment began and where hygiene ended. An amendment disapproving of these centres providing consultations and advice for mothers and young children belonging to classes of the community who are quite able to consult their own family doctor was carried by a very large majority.

Sir Ewen Maclean, Chairman of the Committee on the Causation of Puerperal Morbidity and Mortality, moved the adoption of the report on that subject. The original reference to the Committee was "to consider and report on the causation of puerperal morbidity and mortality and on the administrative action, if any, that should be taken in connection with the matter." The Committee had received valuable information from various quarters, and the treatment of the subject was being closely watched both by

interested bodies in this country and by colleagues overseas, who found themselves face to face with the same important problem. In the course of the proceedings an important conference had been held with representatives of practically every body, statutory and otherwise, directly concerned with the problem. Two committees had been set up by Government, one to consider the working of the Midwives Act, and the other to consider the application to maternal morbidity and mortality of the medical and surgical knowledge at present available, and to inquire into the need and direction of further research work. In addition to these two Government Committees, however, a committee of the British Medical Association was still needed to receive all possible information on this subject and to safeguard the interests of the profession. Moreover, it was pointed out that figures from the maternity departments of the great hospitals in London, Glasgow and Birmingham showed a reduction in mortality of from 4 to 1 per 1,000 cases. The report was generally approved.

A motion by Mr. David Lees (Edinburgh) to secure the proper control and treatment of venereal disease by conferring on medical practitioners and local authorities a power of placing a "compulsory" on all persons infected with venereal disease was negatived by a large majority.

The scientific sections of the Association were well attended. There was an interesting discussion on the subject of Volkmann's "Ischæmic Contracture," which was opened by Sir Robert Jones, and was of special significance in view of the recent decision of the Assize Court in the case of Tyndall v. Alcock. A joint session of the Surgery and Radiology sections discussed "The fallacy of x-rays in abdominal diagnosis." In the section of Mental Diseases and Neurology, Professor W. Weygandt, of Hamburg, read a paper on "Autotoxæmia as a factor in the causation of the psychoses."

The Annual Dinner of the Association was well attended, five hundred persons including ladies, sitting down, under the presidency of Sir Ewen Maclean. On the following day a congregation of the University of Wales was held when the degree of Doctor of Laws *honoris causa*, was conferred upon Dr. H. B. Blackenbury. Sir Thomas Lewis (London), Sir Robert Philip (Edinburgh), Dr. W. W. Chipman (Montreal), Sir George Syme (Melbourne), and Dr. Franklin Martin (Chicago). Among Canadians who were at the meeting were General Bukett, C.B., Dr. A. D. Blackader, Dr. W. W. Chipman, and Dr. J. D. Adamson.

Provincial Association Notes

ANNUAL MEETING OF THE PROVINCE OF QUEBEC MEDICAL ASSOCIATION

This Association had a very successful gathering at Sherbrooke on September 18th, which was attended by some three hundred physicians from various parts of the province. Both the English and French profession were represented, and foregathered in a way that was of very happy augury.

The first part of the morning was taken up with clinics, operations, and practical talks at the St. Vincent de Paul General Hospital. Surgical operations and discussions of operative technique were conducted by Drs. Ledoux, Bertland, and Gandet. An eye, ear, nose and throat clinic was given by Drs. McCabe and Plante. Infantile paralysis, Bordier's treatment, x-rays and diathermy were discussed by Dr. F. A. Gadbois. The importance of pre-natal examinations and their bearing on gestation and prognosis was well presented by Drs. H. C. Cabana and A. A. Migneault. Drs. Cabana and G. L. Favieau, at the Anti-venereal Dispensary No. 5, gave practical instruction in the staining and examination of material for gonococci, and also on the preparation of intravenous injections

and the technique of their administration. They also discussed the complications and treatment of gonorrhœa, and showed patients demonstrating the results of treatment in the various stages of syphilis. Dr. R. L. Duberger demonstrated some of the most important chemical tests in connection with the blood and urine.

The principal addresses were given later in the morning by Dr. C. Jeannin, Professor of Obstetrics in the University of Paris and Dr. F. Lahey of Boston. Professor Jeannin's subject was "Eclampsia," which he developed very thoroughly. It is expected that the full text of his most valuable address will be published in the next issue of our *Journal*.

Dr. Lahey discoursed on "Abdominal surgery and the general practitioner." He pointed out the importance of diagnosis in abdominal conditions, for most cases requiring operation were first seen by the general practitioner. The final result depended very frequently on his alertness. Dr. Lahey referred in some detail to the most commonly met with abdominal disorders.

In dealing with gastric and duodenal ulcer Dr. Lahey considered that from a diagnostic standpoint both were the same. In both, pyloric spasm was the cardinal feature. The differential

diagnosis from other painful abdominal conditions was dealt with and its importance emphasized. Only by accurate work could the propriety or otherwise of surgical intervention be determined. Unless in an emergency the treatment was essentially medical at least at first. Three points were insisted on: absolute rest in bed for three weeks, a liquid diet and sufficient alkali to neutralize the attendant hyperchlorhydria. After apparent cure the patient should remain on his special diet for one year. In cases where it was impossible to maintain this regimen either on account of the lack of co-operation on the part of the patient or the exigencies of his occupation, operation might then be considered. There was a difference of opinion among surgeons as to the relative advantages of partial resection of the stomach and gastro-enterostomy. The latter was an operation of drainage and the disadvantage was chiefly in the tendency to the formation of new ulcers in various parts near the anastomosis. Dr. Lahey expressed his preference for gastro-enterostomy and thought that partial gastrectomy should be kept for the cases associated with bleeding that could not be controlled by other measures.

Cholelithiasis was then discussed. This condition always called for operation, as when stones were not removed serious organic changes always supervened. Emphasis was laid on the necessity of exploring the common duct in order to determine the presence there or otherwise of other stones, which were often there when least expected. If stones in this situation were overlooked symptoms would continue.

Persistent painless jaundice, with dilated gall-bladder in the vast majority of cases meant cancer. Operation then was not indicated except as a palliative measure. Usually the disease had progressed too far to be eradicated.

Dr. Lahey regarded the common diagnosis of "chronic appendicitis" with considerable scepticism. This affection was not nearly so common as it was thought to be. This diagnosis should never be made unless there was a clear history of an acute attack of appendicitis, followed by persistent soreness in the right side of the abdomen. Many operations done under this erroneous diagnosis were futile.

Dr. Lahey also spoke briefly on the subject of double hernia and of the merits and demerits of the various operations devised for the relief of this troublesome condition.

The afternoon was devoted to entertainment, there being golf, afternoon teas for the ladies, and a very pleasant trip on Lake Memphremagog.

In the evening a banquet was held at the Frontenac Hotel, at which more than two hundred and fifty physicians were present. Dr. Gordon Hume, the President of the Sherbrooke

Medical Association, was master of ceremonies. The principal addresses were given by Dr. C. F. Martin, Dean of the Medical Faculty of McGill University, and Dr. L. G. H. Harwood, Dean of Medicine in the University of Montreal.

Dr. Martin commenced his remarks by vouching that all the doctors present realized the great opportunity offered in this province to the medical profession through having the two great schools of medicine centred here, the one French and the other English. The two had a different technique and a difference in their methods of approach to teaching but he could vouch for the fact that the English school respected the French method and he believed the same *mutatis mutandis* was the case with the French doctors. With all the facilities we have in our schools of medicine we could lead the Dominion if we would only work together in accord and co-operation. We must have greater trust in each other. The English doctors agreed that there must be no encroachment on the autonomy of the French-Canadian medical profession and, granting that, there was no reason why we could not together do very great things. He was surprised to see that after one group of doctors had formed an association of industrial medicine another group had formed another association. He did not express himself in favour of either one of these groups but what he did want was to see the two united.

Dr. Martin thought that at the present day too much stress was laid on laboratory methods and that the old-time clinical methods of examination and the careful taking of case-histories were being neglected, to the detriment of the patient. In closing he declared that the Province of Quebec was apt to languish under an inferiority complex which must be overcome if the greatest good was to come to the medical profession here.

Dr. Harwood expressed complete agreement with Dr. Martin in his view that too much emphasis was placed on laboratory examinations and on the necessity of greater co-operation in medical work on the part of the two races.

After the banquet was over the assemblage adjourned to the City Hall where the business matters were transacted. The President, Dr. J. Stevenson, of Quebec, was in the chair. Apart from the election of officers, only two matters of importance came up. Dr. G. Stewart Cameron, of Peterboro, Ont., was present, as representing the Canadian Medical Association in bringing to the attention of the Quebec men the proposed institution of a Canadian College of Physicians and Surgeons. It was not proposed that action on this matter should be taken at once, but it was brought forward merely for information and consideration. Dr. Cameron explained that the proposed college was for the purpose of enabling the giving of post-graduate diplomas

in Canada for Canadian doctors. At present it was pointed out Canadians have to go to the United States and elsewhere for recognition of special excellence and the new body would conduct post-graduate examinations itself without interfering with the training of medical students under provincial regulations. When it was made clear by Dr Cameron and Dr Stevenson that examination for the post-graduate diploma of the college would be conducted in both French and English, and that the French universities would be given adequate representation on the Council of the College, the proposals seemed to meet with general favour. Drs L. T. Pariseau and P. Z. Rheame, of Montreal, supported the idea effectively.

The recently amended Workmen's Compensation Act then came up for discussion. Dr Côté outlined the provisions of the new law, which was now effective, and Dr J. E. Belanger, of Lauzon, endeavoured to explain its operation. After a very animated discussion, during the course of which much dissatisfaction with the law was expressed by some of those present, the meeting dispersed without any action being taken.

Under the circumstances it would appear wise to give here some additional information on this matter.

The Quebec Workmen's Compensation Act has been in operation since September 1, 1928. So far as can be judged from its provisions, as well as from the new tariff of medical fees, it seems to indicate distinct progress in labour legislation. The Commission appears to be strong without being unwieldy, and the choice of Dr J. E. Belanger as its Chief Medical Adviser meets with the unqualified approval of the medical profession of the province, and particularly those who have already had dealings with him in his capacity of President of the College of Physicians and Surgeons of the Province of Quebec. In the successful administration of the Act the Commissions have asked for the full co-operation of all the members of the medical profession of the province, and have assured them that they will not countenance any attempt on the part of the various groups to exploit the Act. The new tariff, if anything, is on the side of generosity, and Dr Belanger and Dr Vezina are to be congratulated for the care they have taken in its preparation to meet all contingencies. Notwithstanding the noisy criticism of a small and relatively unimportant group at the annual meeting, the overwhelming sentiment of the members of the Province of Quebec Medical Association, as well as of the members of the Industrial Medical Association of the Province of Quebec and the Association Canadienne de Médecine Industrielle, which met the same day, was strongly in favour of giving the Act a fair trial and supporting it in every way possible.

The best advice that can be given our professional brethren in the Province of Quebec is to continue to display the traditional respect for constituted authority for which Quebec is noted, by supporting the Workmen's Compensation Commission, and assisting them in every way possible, and by refraining from criticism, if things do not all work smoothly during the first year, to have patience, and remember that during our early years we all fell many times before we learnt to walk.

Before closing a note of warning should be sounded. If certain of our professional brethren are expecting to feather their nests with the proceeds of unjust and exorbitant fees they will be disappointed. It must be clearly understood that while the medical profession will play a large and important part in the administration of this Act, and in fact will collect about 20 per cent of money expended directly or indirectly by the employees, this Act, as well as all Workmen's Compensation legislation, is put through at the instigation of and for the benefit of the working man, and that as the present Provincial Government did not hesitate to eliminate the legal profession from the Act it would, if the medical profession do not play the game, take measures to institute some form of state medicine to handle industrial accidents. We have, however, confidence in the good sense and honesty of the bulk of our profession, and do not consider that there is much danger of this occurring. We wish the new Commission and our confidant Dr Belanger success in their thankless and difficult task.

The following officers were elected for the ensuing year: President, Dr B. Bourgeois, Montreal; Vice-Presidents, Drs E. C. Cross, Three Rivers, P. C. Dagneau, Quebec, and H. C. Cabana, Sherbrooke; Secretary, Dr Léon Gém-Lajoie, Montreal; Treasurer, Dr T. Trottier, Montreal.

THE INDUSTRIAL MEDICAL ASSOCIATION OF THE PROVINCE OF QUEBEC

The growth of interest in industrial medicine is shown by the formation of the Industrial Medical Association of the Province of Quebec. This originated in a meeting of physicians interested in this work, which was called by Dr C. F. Martin, Dean of the Medical Faculty of McGill University, in January of this year. The original idea of the meeting was to organize an extensive course for those interested in industrial hygiene. The Universities of Laval and Montreal were asked to send delegates with a view to obtaining their support and co-operation in the scheme.

The Association was organized, with Dr A. R. Pennoyer as the President, but no further meet-

able solution of the problem he threw out a few suggestions "Of only one thing I am certain," he concluded, "and that is that the solution should be sought and found within the profession, and not some scheme forced upon us, which will injure our prestige, cripple individual initiative, and cease to attract to our medical schools the idealistic and visionary students who have always been the leaven of the profession."

Dr E A McQuade, President of the Ontario Medical Association, brought fraternal greetings from his organization. This act of courtesy from the Ontario body and Dr McQuade's brief but witty remarks were greatly appreciated.

The afternoon was devoted to diagnostic clinics: one on syphilis, eczema and malnutrition in children, by Dr F F Tisdall of Toronto, one on elephantiasis of the leg in a 16-year old boy, one on prostatic obstruction by Dr Roscoe Graham, and a medical clinic by Dr J C Meakins.

In the evening Dr Harry Lewis gave a dinner to the eastern guests and the executive committee at the Manitoba Club.

On Tuesday morning Dr Primrose gave an interesting paper on "Tumours of the breast," the discussion being led by Dr W J Harrington of Dauphin. The next hour was devoted to infantile paralysis, a timely topic on account of the prevalence of an epidemic in the city, with more than one hundred and sixty cases and thirteen deaths.

Dr F F Tisdall differentiated between the form of the disease which is accompanied by gastro-intestinal disturbances and the true paralysis. The rapidity of development was a difficult factor in checking the disease. On the first day the patient manifested only the ordinary symptoms of most infective processes, but poliomyelitis patients, even from the start were characterized by a peculiar appearance. The eye took a glassy look, the patient was somewhat dazed and at the same time nervous. On the second day there was usually stiffness of the neck and back and within two to four days paralysis of the muscles set in. It was rare for paralysis to start after the seventh day, and death usually came within seven days, if at all. The drowsy patients were in less danger of death than the lively ones. He commended the Manitoba physicians for their prompt use of convalescent serum. Muscular injections were safer and advisable in the early stages, but when the disease was advanced quicker action could be obtained by spinal injection.

Dr Tisdall stressed the need of medical attention during the acute paralytic stage of the disease. One third of hospital cases were due to faulty care. The arms should be kept strapped up and the legs straight. He warned against massage in the acute stage. It did more harm

than good as no strain should be put upon muscles infected by the poliomyelitis virus. Electrical treatments of any kind were valueless.

Dr J M McEachern opened the discussion with a description of the present outbreak in Manitoba. It was slower in development than usual. Paralysis did not set in so quickly, but took from two to five days. Twitching of the limbs indicated the start of paralysis. In the early stage patients showed a distinctive appearance which Dr McEachern described as dazed but lively. Serum showed an immediate effect in reducing temperature and medical men here were convinced that it has a deterrent effect on paralysis.

Dr O J Day believed the disease which was accompanied by gastro-intestinal upsets, but did not reach the paralytic stage, should not be called poliomyelitis. Every year there was a slight outbreak of this with a few cases of paralysis but this year it had grown to the epidemic stage. He agreed with other speakers that contagion by contact was proved in the present outbreak.

Dr A A Murray described the apparatus used in the treatment of paralysis. The muscles should be relieved of all strain and thus required constant medical attention. The limbs should be adjusted to take the strain off the affected parts. In the case of paralyzed arms the patient should be kept strapped for many weeks, and where the legs were paralyzed patients should not be allowed to walk for months. Many hospital cases were due to relaxing treatment too soon. There was hope of improvement in muscles for two years after the onset of paralysis.

At 11 o'clock the session adjourned to see a motion picture at the Orpheum Theatre on "Effects of radiation on cancer cells." This film was prepared under the direction of Dr Cant of St Bartholomew's Hospital, London, and was presented by Dr J Miller, Director of the Richardson Laboratories, Queen's University. He also discussed the technical phases of the new radiation treatment. It is hoped that Prof Miller may be induced to show the film again in Winnipeg on his return from the Pacific coast.

Following luncheon, Dr Ross Millar conveyed greetings from Hon Dr J H Knig, federal minister of health and asked for the close co-operation of the Association in the fight against the drug traffic and the abuse of narcotics. Dr Harvey Agnew mentioned that there are 550 hospitals in Canada, with a capacity of 52,000 beds and a budget maintenance of approximately \$50,000,000. The building budget was the same in proportion to the population as in the United States, where it amounted to about \$1,000,000 per day. The great need at present was for greater hospital accommodation.

President, Dr F H Huilburt, North Battleford, First Vice-President, Dr W A Dakin, Regina, Second Vice-President, Dr E R Myers, Saskatoon, General Secretary-Treasurer, Dr A MacG Young, Saskatoon Dr J B Ritchie, of Regina, was re-elected as the Asso-

ciation's representative on the Anti-Tuberculosis League Board Dr Lillian Chase, Regina, Dr T W Walker, Saskatoon, Dr Gordon Young, Moose Jaw, were named as our representatives on the Editorial Board of the *Canadian Medical Association Journal*

Medical Council of Canada

THE ANNUAL MEETING OF THE COUNCIL

The sixteenth annual session of the Medical Council of Canada was held in Ottawa at the Chateau Laurier on September 5th. Out of a total Council of thirty-three representatives there were twenty-nine present this year, a record attendance.

The following answered the roll call:

Governor-in-Council representatives: Dr P A McLennan, Vancouver, Dr W A Thomson, Regina, Dr H A Lafleur, Montreal.

From British Columbia: Drs Seldon and Bonnell. Alberta: Drs H McGill and W S Galbraith. Saskatchewan: Drs A M Young and D S Johnstone. Manitoba: Drs Thornton and Rogers. Ontario: Drs W Spankie and Argue. Quebec: Dr A Simard. New Brunswick: Dr Van Wait. Prince Edward Island: Drs MacMillan and Tanton. Nova Scotia: Dr MacDougall.

From University of Alberta: Dr D G Revell. University of Manitoba: Dr S W Prowse. University of Western Ontario: Dr J W Crane. University of Toronto: Dr J M MacCallum. Queen's University: Dr J C Connell. McGill: Dr C F Martin. University of Montreal: Dr L deL Harwood. Dalhousie University: Dr J Stewart. The homœopathic profession was represented by Dr Morgan of Montreal, Dr Becker of Toronto, and Dr J P McCormick of Edmonton.

Resolutions of condolence in the cases of the deaths of Dr Normand of Three Rivers, and Dr Warburton of Charlottetown, members of the Council who had died during the past year, were duly passed and recorded by a silent standing vote of the Council.

The president, Dr Spankie of Wolfe Island, addressed the Council in general terms, and the Registrar, Dr R W Powell, of Ottawa read his report to Council as to the activities during the preceding twelve months. The Council then proceeded to transact the necessary business pertaining to its functions, such as the creation of

examining Boards for the ensuing year and the fixing of the centres for the examinations of candidates in 1929.

At 2 p.m. a delegation from the Canadian Medical Association was received, consisting of Dr E S Ryerson of Toronto University, convenor, Drs Parizeau, Ramsay, Simpson, Austin and G Young. The object of the delegation was to place before the Council a proposition which has been under consideration for some time, having as its object the formulation of a scheme of procedure to unify the examinations required now from candidates, whereby they could present themselves for a single examination for their degree and then license and so lighten their burden, financially and otherwise. This complicated proposition was advanced at this stage in order to secure if possible the sympathetic consideration of the Council on the principle. The delegation was accorded a respectful and sympathetic hearing and it was assured by the President that its representations would receive earnest consideration. Later, it was decided that the time was not opportune to move in the matter. Boards of examiners were appointed to conduct the examinations fixed for June 6, 1929, at eight centres from the Pacific to the Atlantic, and for October, 1929, at Montreal in English and French, and at Winnipeg in English, following the practice for the last few years in that regard. The officers of the Council were then duly elected upon a report of the Nominating Committee as follows: President, Dr G C Van Wait, Fredericton, N.B., Vice-President, Dr W Rogers, Winnipeg, Registrar, Dr R W Powell, Ottawa, Auditor, Geo L Blatch, Ottawa, Bankers, Canadian Bank of Commerce, Ottawa. The next meeting of the Council was fixed for September 4, 1929.

The customary votes of thanks were passed and tendered to the various universities, hospitals, etc., from whom the Council had received such assistance and courteous treatment during the past year. The session then adjourned after the rendering of the National Anthem.

Special Articles

ULTRA-VIOLET RADIATION FOR THE GENERAL PRACTITIONER

By R. KING BROWN, B.A. M.D., D.P.H.

(IV)*

"In my last article I dealt with the sources of ultra-violet radiations, and to those who peruse it it will be evident that for the general practitioner the weight of evidence seems on practical grounds in favour of the mercury vapour lamp, at least to begin with. It is cheap to run on account of the low amount of current required, and the exposures must be short since the output of ultra-violet rays is very large compared with those producing light and heat, and this enables a larger number of patients to be treated within a given period. It is advisable to have a supplementary source for heat rays, both visible and invisible, but this is not absolutely necessary, since the heat of the room in summer time will be sufficient and in the winter the room can be heated by a gas fire.

"Coming now to the practical application of our theoretical consideration, the following is intended to apply to the mercury vapour lamp, but can be used also for the arc lamp by lengthening the exposures to the latter according to the amperage of the lamp which regulates the intensity of the output. One must also bear in mind that the intensity varies inversely as the *square of the distance* from the source of light, so that if you double the distance you only get a fourth of the intensity. Before commencing, one must decide whether the light bath is to be general or local, or whether you are going to give merely a mild stimulating dose—called by Thederling a 'light douche,' or a medicinal dose, *i.e.*, one which will produce a mild or severe erythema.

"If you intend to give a general bath, the patient should be stripped with the exception of a pair of bathing drawers, and the eyes should be protected by dark glasses. A good distance to commence with is one metre or a yard. The first exposure should never exceed *one minute* front, *one minute* back, and a *half to one minute* on each side of the trunk, but much will depend on the condition of the patient, especially in regard to pigment. Very fair patients or albinos must have a minimal dose—indeed half this in albinos. If, however, a patient has a brownish or olive complexion, showing a likelihood of being a good pigmenter, the first bath may perhaps run to $1\frac{1}{2}$ minutes all round. Should this first exposure produce no signs of an erythema the next bath may follow in a couple of days, and the exposure may be doubled. Should an

erythema occur, however, the second bath should not be given for four days, or until the erythema has completely disappeared. After this has happened, the times in the second bath may safely be doubled.

"It should be remembered, however, that the length of the second and subsequent baths depends entirely on the reaction of the patient's skin to the first bath, and it is always a good plan to use this as merely a trial run, to find out the sensitiveness of the patient's skin to ultra-violet rays. After doubling the second bath, the following baths may be increased by one minute each time up to about five minutes front, five minutes back and about three minutes on each side.

"As to the number of baths a week, as a rule two are sufficient, and it is not necessary to produce an erythema every time. In special cases one may exceed the five minutes, but this is not as a rule necessary or advisable. It is better as a general rule to decrease the distance down to two feet or less as soon as the resistance of the patient is well established.

"Another point to be borne in mind is that the light, as previously stated, acts very like a vaccine, and is followed in the next day or two by a negative phase. The dose, therefore, should not be repeated till this is quite over, and the immunity is at its height, which will be in from two to five days, according to the degree of erythema produced. In some patients, especially the middle-aged and old, this is accompanied by a good deal of mental depression, which is most evident on the second day. Should this occur, or be likely to occur, the patient should be told to rest as much as possible the day after an exposure.

"To avoid this, Eidenow recommends that an erythema dose should only be produced on one quarter or one sixth of the surface of the body at a time, a fresh quarter or sixth being chosen every second or third day till one arrives again at the first section exposed, when it will be again in a receptive condition. Whatever plan is adopted it is wise to underexpose till you know your patient, and to treat each patient as an individual and not according to any rigid scheme.

"There is no very sharp distinction between the local and the general bath, but a maximum local area (such as the lower part of the spine) would comprise an area of about eight inches square. In producing an erythema in a local area for special pain, such as sciatica or neuritis, the same precautions are necessary as in the general bath, but the effects remain local, and the patient is not likely to suffer from constitutional symptoms such as depression the following day.

"If you decide to give a light douche, the first exposure may be one-half to one minute back and front at one metre, and the latter figures need not go beyond two minutes back and two minutes

* Article I, *Canad. M. Ass. J.*, March, 1928, xviii, 326, Article II, *Ibid.*, April, 1928, xviii, 465, Article III, *Ibid.*, July, 1928, xix, 99.

front about twice a week. In this way you get a tonic effect only, there is no negative phase and no depression, but, of course, if special disease, such as some form of surgical tuberculosis, be present, the dose is not sufficient to produce any marked effect, beyond some improvement in the general health.

"The last point now to be considered is, in what diseases are we likely to produce cure or improvement? The answer to this is very difficult, since much of the work at present is of an experimental and empirical nature. There are, however, a few diseases which can be definitely cured or improved by light treatment, and a great many more in which a certain percentage will show cures.

"The two groups most amenable to treatment by light are undoubtedly (1) diseases associated with defective ossification of the bones, and (2) various forms of surgical tuberculosis. Under (1) we may include rickets, osteomalacia, and fractures which show little tendency to unite, and under (2) diseases of the bones of the spine, joints, skin, in fact most forms of tuberculosis

except pulmonary. In this latter complaint, it is best not to attempt using the mercury vapour lamp until some suitable and safe technique has been worked out by the experts.

"There are many other diseases improved or cured, and one may state generally that, as the light treatment enables the skin to produce immune bodies, most diseases in which there is some form of sub-acute or chronic bacterial infection will be benefited by its judicious use. As a general rule fever caused by these infections should be allowed to subside before attempting to give ultra-violet irradiation.

"The contra-indications that we have here are, therefore, pulmonary tuberculosis and fever. To these may be added kidney disease, certain forms of heart trouble, and advanced arteriosclerosis. It may lastly be stated generally, that, if reasonable precautions are taken in giving ultra-violet irradiation it will be found of great benefit to general health, will cure many complaints, and will not injure those it fails to clear up"—(*Brit J Actinotherapy*, 1928, iii, 108)

Topics of Current Interest

LORD BALFOUR ON SCIENCE AND PHILOSOPHY*

"Lord Balfour, as President of the British Institute of Philosophical Studies, delivered an address at their third Annual Meeting, on July 16th, dealing mainly with the philosophic problems arising from the advance of physical science. His words deserve consideration from all who, like members of the medical profession, are daily involved in the difficult task of reconciling the apparent, as suggested by perception, with the real, as partially disclosed by an incomplete science. It is perhaps appropriate at this juncture to remark on the peculiar fitness of Lord Balfour, who has recently attained his eightieth birthday, for the part of mediator between the point of view of the world at large and that of the laboratory and the study. His first philosophic work was written some fifty years ago, and his experience as a Minister of the Crown goes back almost forty years. In view of these circumstances, and of the known clarity of his mind, his address is of unusual interest, he took as his text some words of Professor L. T. Hobhouse: 'Philosophy does not consist in pieces of knowledge, but primarily in an attitude, a desire to understand and appreciate.' Lord Balfour agreed with this statement, and proceeded to discuss two of the problems which one should understand and appreciate—the problems of perception and induction. The plain man would ask what there was specially requiring to be understood in such simple matters. Perception

and induction were fine names for the simple operations of observing the world in which we lived and drawing conclusions from our observations. Mankind was always doing it, mankind had always done it, and with the progress of natural science they would do it more successfully every year. So, said Lord Balfour, thought the plain man. But it was just science that was the cause of their troubles. In pre-scientific days formal logic, morals, metaphysics, and metaphysical theology chiefly occupied the thoughts of philosophers, to these had now been added problems raised by physics, and these all involved perception and induction. Taking, as the most important and most obvious kind of perception, perception by seeing, the speaker described the complex train of causes and effects underlying this process—the emission of energy by electrical charges from matter, the propagation of ethereal waves, followed or accompanied by the psychophysical process, which, in each individual case, converted the physical message into a mental perception. There was a monotonous simplicity, continued Lord Balfour, about the world he had attempted to describe, and it could not be pictured as possessing either beauty or variety. But it was not merely aesthetically unattractive, it had the further defect of possessing no resemblance to the world they saw. The more they knew what reality was, the less did natural fact harmonize with perceptual experience. In these circumstances, he asked, what became of experience, and by what process of logical legerdemain was science extracted from observation? They lived in a world of illusions, how, by observing such a world, did they succeed in reaching

* *Brit M J*, 1928, ii, 163

realities? This was one form of the second question—namely, What is induction? The inductive logic which should justify the inference of general laws wholly from particular observation, even when the observations were admittedly valid, had, in his opinion, still to be discovered. What were they to think of such a task when the observations were admittedly invalid? What were they to say of the self-satisfied theorizing of the eighteenth and nineteenth centuries now that seeing had not only ceased to be believing, but was in open revolt against it? He would make no attempt to solve these difficulties, it sufficed if he had succeeded in giving some support to Professor Hobhouse's statement. Lord Balfour concluded 'I do not suggest that it is every man's duty to be a philosopher, or to spend his time speculating about the universe. I do suggest that those who make no effort to get beyond the teaching of common sense should do so in no boastful or self-confident spirit. Whenever they find common sense opposed to science, let them throw in their lot every time with science. To the man of science, on the other hand, I would say that science, though on the way to truth, is always incomplete and not always true, and that in the present state of our intellectual development its ultimate basis, deeper even than experiment and observation, is faith.' Could there be, he asked, a better justification for the existence of such a society as theirs?"

MEDICINE IN ART

The popular lecture at the last meeting of the British Medical Association, was delivered by Sir Berkeley Moynihan, on the subject of "Medicine in Art," before a large and appreciative audience. We extract the following report of this lecture from the *British Medical Journal* (August 4, 1928).

"Sir Berkeley Moynihan began by remarking on the heavy load of responsibility which the medical man had to carry. The doctor held in his hands the health and lives of his fellow creatures. When he ended his arduous day's work—a work which had made huge demands upon his nervous as well as upon his physical energies—he realized often that virtue had gone out of him. Even if he failed to realize it, it was none the less true. That store of virtue could be replenished in no other way so well as by the contemplation of things of beauty. It was of little use to play the indifferent round of golf or indulge in some other form of physical exercise, he had better devote himself to some quiet contemplation of art—beautiful furniture, china, pictures, books. Here was indeed rest for the weary mind. The lecturer then went on to speak of how the alliance between art and medicine was foreshadowed by the Greeks, how in the Greek mythology Apollo, the god of light and giver of life, was also the god of medicine, and bestowed on his favourite son, Æsculapius, the divine gift of healing. The association

between art and medicine, thus begun, had been carried on in some of the works of the greatest artists, of which he proceeded to give examples. He began by showing some representations of deformities in sculpture—in the gargoyles of cathedrals, for example—and then passed to the innumerable examples in mediæval painting of devil-possession and exorcism. People in the throes of such possession had been depicted by Raphael and many another, with more or less truth to the recognized picture of hystero-epilepsy. He commented upon the extraordinarily widespread and long-standing prevalence of the idea of an interior 'not ourselves.' Indeed, one found the same thing in Socrates, with his 'divine sign,' and Joan of Arc, with her 'voices,' not to speak of Sir James Barrie's 'M'Conachie' or the Irishman's 'Flanagan.' The idea of 'somebody else inside us' went right through the art of the Middle Ages. No testimony in a law court to-day was more confidently advanced and more unquestioningly accepted than the testimony in old time as to spirit-possession. It was vouched for by troops of witnesses. People said on oath and under torture that they had actually seen the evil spirits which Reubens and other artists grotesquely represented as being exorcised from the head or out of the mouth or fleeing the church. Even from far-away Peru he was able to show the representation of a female skull which had evidently been subjected to primitive trepanning for no other purpose than to allow of the escape of the evil spirit.

"Next came a series of studies of emotional expressions, including some by Sir Charles Bell, one of the greatest artists that the profession of medicine had produced. This series naturally included Reynolds's famous picture of John Hunter in reverie. Another example was 'The ecstasy of St Jerome,' in the Louvre, which the lecturer declared to be the picture that, of all others, had the greatest effect upon himself. Nothing in the world spiritually did him so much good as to spend a few moments on every visit to Paris in contemplation of that work. He concluded with a few pictures showing how artists depicted diseases, among them achondroplasia. Curiously enough, the achondroplasia was invariably represented as being in charge of animals. Then there were such deformities as club-foot, a drawing of which was found at Luxor dating from 2500 B.C. Chronic rheumatoid arthritis existed in Egypt very badly, said the lecturer, in the period of the dynasties. Hydrocephalus and acromegaly were other abnormalities represented in art. Rodent ulcer was depicted in one of Albert Dürer's engravings, dated 1502. A delightful picture was one by Franz Hals, showing the operation for removal of sebaceous cyst from the scalp. The expressions of both patient and surgeon were eloquent, the patient in extreme apprehension, while the surgeon took the proceedings with quite phenomenal calm—very unlike Astley Cooper, who removed a sebaceous cyst from the King's scalp, and spent the ensuing

days in a dreadful state of anxiety lest anything should befall the royal patient. In the Franz Hals picture, by the way, the doctor's diploma is shown hanging on the wall, and, to make matters doubly sure, the surgeon was wearing a replica of it in his hat! Sir Berkeley Moynihan concluded by saying that the medical man, visiting galleries abroad or at home, could, from his professional knowledge, find much to interest him in the details of many pictures which were not apparent to the ordinary public. Moreover, as he had said at the beginning, the contemplation of beautiful things did help him in his daily work, and it was well for every devotee of Æsculapius to turn aside now and then and worship at the shrine of his father, Apollo.

"Sir Ewen Maclean, who presided at the lecture, and Dr C O Hawthorne both expressed the thanks of the gathering to the lecturer, the latter remarking that what Sir Berkeley Moynihan had said about the use of leisure for the study of art filled him with a certain sadness at his own wasted opportunities. In responding to a vote of thanks, Sir Berkeley Moynihan said that it had been a privilege to give the address to an audience so attentive. It seemed to him that the big and important concerns in one's life, which might be likened to the bricks in a wall, needed to be held together by something scarcely visible, the mortar filling the interstices. These things, these interests, of which he had been speaking that evening, were the mortar between the bricks. Surgery was not merely a craft or a science, it was something bigger and better than either or both. It was a spiritual devotion, and in order to set it forth as an example recourse must be made constantly to some spring or well of refreshment. That was why he had rejoiced in the opportunity that evening, not so much to show pictures or to talk more or less trivial tittle-tattle, but to put into the minds of his colleagues in the profession that this way of refreshment was open to them."

MEDICAL EDUCATION IN THE UNITED STATES

MEDICAL STUDENTS

The number of medical students, this year, was 20,545, an increase over the previous year—an increase which has persisted since 1919, when the enrolments of students reached the lowest ebb (12,930) as a result of the reorganization of medical schools. Mergers of medical schools were urged whereby an oversupply in numbers might give place to a smaller number of better equipped institutions. The entrance requirements also were increased to include two years of college work in order that medical education in this country might be on a par with that of the leading nations abroad. The reduction in the numbers of students resulting from these changes was not as great as was expected. The subsequent increase in the enrolments is of students who have

not only met the higher entrance qualifications but also, for the most part, voluntarily obtained baccalaureate degrees prior to or during their medical course.

STUDENTS FAILING TO GRADUATE

Statistics published this week show that, of the students enrolled during the nineteen year from 1907 to 1926, inclusive, 83 per cent obtained their medical degrees and only 17 per cent failed to graduate. It is interesting also to know that 90 per cent of those who did not graduate dropped out, voluntarily or otherwise, during the first two years of the medical course.

MEDICAL GRADUATES

The number of students who graduated in 1928 was 4,262, as compared with 2,529, (the lowest number in the decline), who graduated in 1922. In six years, therefore, a rapid increase in the numbers of graduates has fully offset the decrease of the eleven years prior to 1922 and, at the same time, 96 per cent are from class A medical schools, as compared with less than 60 per cent in 1911. With the closer relations with hospitals and outpatient departments, the use in clinical instruction of section clinics and clinical clerkships, and the use of autopsies and clinico-pathological conferences, these graduates have obtained a clinical training far surpassing that of twenty years ago. More than 90 per cent of all graduates now obtain internships in approved hospitals. Before beginning practice, therefore, a graduate in medicine has spent three years in the examination and care of patients and has seen more patients than many see in ten years of private practice. Twenty-five years ago in their undergraduate instruction students obtained little experience in examining patients, and most of them did not receive hospital interne training.

MEDICAL SCHOOLS

Since 1922 the number of medical schools in the United States has fluctuated between seventy-eight and eighty. The two Missouri institutions whose charters were revoked are still issuing degrees under new charters and names. With the gradual strengthening of the methods of licensure however it is believed that the end of low grade medical schools is not very far away. There are now seventy-two medical schools in class A, with the admission of Temple University School of Medicine to that class. Two medical schools remain in class B and six in class C. The University of Southern California has declared its intention of reopening the medical school this fall, and next year the new medical school of Duke University will be opened. Some of the state university medical schools now offering two years of the medical course are also planning to teach the clinical years. During recent years the tendency in medical schools has been to concentrate teaching in new and enlarged plants whereby the laboratories will be in closer contact with clinical teaching. Through these larger

plants, coupled with more teachers, more laboratory equipment and more abundant clinical material, the eighty medical schools have been enabled, during the last six years, to increase their total enrolment from 14,000 to more than 20,000 students. It is believed that they will maintain an ample capacity to care for all properly qualified students who apply for admission — (*J Am M Ass*, 1928, vol, 500)

MEDICO-LEGAL INSTITUTES

"In the *Lancet*, July 28, an editorial (A Medico-Legal Institute for London, *Lancet*, 1928, ii, 173) deals with the need for a medico-legal institute in London. It is stated that London is one of the few of the considerable towns in the world without a medico-legal institute. Apparently it was not known to the writer that in the United States there is not yet a single establishment that corresponds to a fully equipped and organized medico-legal institute like those discussed in the ninth series of *Methods and Problems of Medical Education*, issued lately by the Rockefeller Foundation, which contains descriptions and accounts of the work of twenty-four medico-legal institutes, mostly European. These institutes for the most part are departments of universities and are housed and organized much in the same way as departments of anatomy or physiology. Naturally the functions of medico-legal institutes will vary somewhat in different places, but their main business is to study medicolegal problems by scientific methods and in all cases the problems will relate in greater or less degree to deaths from unknown or violent means and to diverse aspects of crime against the person. This kind of work, the social value of which does not need particular emphasis, demands special study and training if it is to be done properly. It concerns a special field of medical science and, like all other special fields, requires steady devotion if society is to reap the full benefit of accumulated knowledge and experience and new progress is to be made. As pointed out in the *Lancet*, to call in the nearest physician or pathologist, even if trained well in an ordinary way, may not be, and usually is not, enough to elucidate properly delicate medico-legal problems. For this important purpose there plainly are needed permanent institutions, manned by trained specialists, in which routine medico-legal examination can be made in the proper way at the same time as investigative and experimental work is carried on to meet unsolved problems and new situations. Crime is progressive, it provides itself with new weapons and means, and hence those who are charged with protecting the community must see to it that their knowledge and skill expand accordingly. This requires the scientific point of view and laboratory facilities. In our country altogether too many medico-legal necropsies are entrusted to physicians who are not competent for that kind of work. Practical politics, as shown by the condition in many of our large cities, is not providing the

proper facilities for progressive modern medico-legal service. Just as in London, there are needed in our larger cities suitable establishments in which medico-legal work can be carried on properly at all times. In addition to post-mortem examinations this work includes toxicological, serological and other forms of investigation requiring expert knowledge. In several places the conditions for making such an establishment at the same time a part of a university would seem to be favourable. This is particularly true of cities in which are located state universities that maintain medical schools. And in New York and Boston, where the system of medical examiner has replaced the coroner and where fairly satisfactory standards of official medico-legal work obtain, the conditions demand increased municipal support in the form of proper housing and equipment. In speaking of medico-legal institutes, it should be noted that there is nothing magical or mystical about the word "institute" which simply means a suitable place for the work in question manned by competent persons who are left in peace to carry on their appointed tasks. As physicians, we have been slow to interest ourselves actively in improving our medico-legal service. Probably the most significant advance in this field so far in the United States is the change from the cumbersome and archaic system of coroner to the much more effective system of medical examiner, which has been made in Massachusetts, New York and New Jersey and which should be introduced as rapidly as possible in other states" (*J Am M Ass*, 1928 vol, 570)

THE CARBON MONOXIDE HAZARD OF THE AUTOMOBILE

"Formerly the dangers of carbon monoxide poisoning were confined to occasional exposure to the gas in mines or about blast furnaces or to asphyxiation with illuminating gas. With the increased use of "water gas," which contains about 40 per cent of carbon monoxide in contrast to the concentration of from 4 to 8 per cent in the old fashioned coal gas, the fatalities have increased. The danger of leaks from the use of inferior rubber hose for gas supply connections has become so serious that the employment of such material is wisely prohibited in some places. However, the principal danger must now be assigned to the exhaust gas from the modern internal combustion engine, of which the automobile is the omnipresent example. The mounting records of deaths in closed places, notably garages, in which the atmosphere is vitiated with exhaust gases have aroused nation-wide concern. It is generally stated that an admixture of more than 1 part of carbon monoxide in 10,000 parts of air (or 0.01 per cent) constitutes a health hazard. Five years ago Henderson and Haggard¹ of Yale University made physicians aware of the possibility of the existence of chronic or repeated carbon monoxide poisoning, to be looked for not

only in the usual places, such as dwellings with leaky gas pipes, but also in streets where motor traffic was very dense. Subsequent reports by Wilson, Gates, Owen and Dawson² seemed to establish further the evidence of a definite street risk of repeated or chronic slight carbon monoxide anoxæmia.

The most recent survey was undertaken by experts of the United States Public Health Service³. Fourteen of the largest cities in the country, having a combined population of more than 19,000,000, were visited and studied at places presumably indicating the maximum hazard from automobile exhaust gas that may exist to-day in metropolitan thoroughfares. The average of 141 tests made in city streets at peak hours of traffic showed a contamination of 0.8 part of carbon monoxide in 10,000 parts of air. Only 24 per cent of all the street samples had more than 1 part of carbon monoxide in 10,000 of air, and in only one location, a covered passageway, was there as much as 2 parts in 10,000. Samples taken inside of autobusses yielded even lower concentrations of carbon monoxide gas. According to these investigators, the figures for street air, when viewed in the light of present-day standards of exposure to carbon monoxide, do not reveal the existence of a health hazard from this source in our city streets. The only person who may possibly be exposed to a health hazard from inhaling street air containing automobile exhaust gas is the traffic officer. This potential hazard may be minimized by diminishing the duration of exposure at the most congested traffic stations. The tests of Bloomfield and Isbell³ indicate, further, that the great danger to life is unquestionably in the small private garage containing one or two cars. Under any circumstances the discharge of an automobile exhaust into a roofed enclosure should be regarded as a hazardous act" (*Jour Am M Ass*, Sept 1, 1928, xci).

EMISSION OF RAYS BY PLANT CELLS

"The latest sensation in scientific circles in Berlin is the discovery that the apex of certain rapidly growing vegetable and animal tissues emit some sort of invisible radiation which has the power to stimulate the growth of living matter with which it is not in contact. When this was first announced, in 1924, by Professor Alexander Gurwitsch, of Moscow, it was received with considerable skepticism here, but now it has been confirmed by German investigators who are

eagerly prospecting the new field of research in various directions.

"Gurwitsch found that if the tip of one of the rootlets of an onion or turnip was fixed so as to point at right angles to the side of another root, though as much as a quarter of an inch away, the cells in the side nearest the tip would multiply more rapidly than elsewhere and so bend the root away. This influence was not due to the emission of some gaseous emanation from the root tip was proved by the interposition of a thin sheet between the two roots. Glass and gelatin sheets stopped the transmission of the growth stimulation power but quartz did not. This is characteristic of ultra-violet rays and Gurwitsch concludes that the radiation from the root tips has a wave-length of 180-200 millimicrons, which would place it among the ultra-violet rays of high frequency.

"The German botanist, N. Wagner, has repeated these experiments with bean and onion roots and measured the effect by counting under a microscope the number of new cells produced in the roots acted upon. The increase is as high as 70 per cent in some cases. Old cells that have ceased growing show the greatest relative increase.

"The German bacteriologist, M. A. Baron, has found that the radiation from onion roots will likewise accelerate the growth of anthrax bacillus and other bacteria. The growing tip of toadstools gives off these same growth-generating (mitogenetic) rays.

"The Siemens Electrical Company has taken up the question and Doctors Hauser and Vahle working in these laboratories report that certain growing animal tissue, such as cancer, emit such rays.

"These results, if confirmed, will radically revolutionize present theories of life and growth. It has hitherto been assumed that the impulse to cell subdivision was somehow due to the direct contact of certain chemical substances transmitted through the tissues, but it now seems that an energy agency is active in vital processes, an immaterial radiation of the nature of light but of too high a frequency to be detected by our eyes" (*Science*, June 15, 1928).

CHEMICAL TESTS ON BLOOD

"The question often arises as to just how active a part the general practitioner should take in the application of the results of our knowledge of the chemical reactions of the blood to his patients. Reed Rockwood (*J Am M Ass*, July 21, 1928), feels that he should be thoroughly conversant with the indications for ordering the tests in various diseases and with the interpretation of the results which are reported from the laboratory as applied to his particular patient but should not take any part whatever in the actual carrying out of the procedures. The indications for chemical tests of the blood and their interpretation are as follows: 1. Never ask

for both nonprotein nitrogen and urea tests in the same patient 2 Except in emergency, never ask for a nonprotein nitrogen determination when the excretion of phenolsulphonphthalein is normal Determine the output of phenolsulphonphthalein first 3 Never ask for the creatinine value of the blood unless the nonprotein nitrogen content is above 60 mg per hundred cubic centimeters Then determine the concentration of creatinine as a matter of routine 4 Order determinations of the uric acid content in cases only of gout or suspected gout 5 Order blood sugar determinations in cases only of diabetes or suspected diabetes or hypoglycæmia 6 Ask for a test of the carbon dioxide combining power of plasma in (a) Diabetic patients with diacetic acid in the urine (b) Uræmic patients

with nitrogen retention and dyspnoea (c) Patients showing toxic symptoms who are receiving large doses of alkali (d) Conditions associated with disturbed motility of the gastro-intestinal tract with marked toxæmia (e) Tetany of all types 7 Order chloride, nonprotein nitrogen and carbon dioxide combining power determinations in all cases of disturbance of gastro-intestinal motility with marked toxæmia 8 Ask for serum bilirubin or icterus index tests in cases of jaundice, but do not pay too much attention to borderland values 9 Ask for blood calcium determinations in cases only of tetany of unknown origin 10 Order inorganic phosphorus tests, if practicable, in cases only of rickets and infantile tetany" (*J Am M Ass*, 1928, xci, 157)

Abstracts from Current Literature

MEDICINE

Über Veränderungen in der Adventitia der Aorta und Ihrer Hauptäste in Gefolge von Rheumatismus (On Changes in the Adventitia of the Aorta and Its Main Branches Following Rheumatism) Chiari, H., *Beitr z path Anat u z allg Path*, 1928, lxxx, 336

The author refers to the well-known "Aschoff bodies" which are found in the myocardium in cases of rheumatic myocarditis Later researches have shown that such bodies, which present many of the features of granulomata, are not confined to the myocardium in acute rheumatism, but may be found in organizing and organized exudates in the pericardial sac Similar nodules, differing only in small details, have also been found in the peripheral portions of the body, in the fatty and connective tissues, and in the neighbourhood of joints Some observations have been made by Fahr and others on rheumatic changes in the smaller blood-vessels, but there have been very few investigations on the condition of the larger vessels

Chiari gives details of seven rheumatic persons dying of various manifestations of rheumatism in whom he examined the aorta and great vessels after death He found in one of his cases a remarkable thickening of the adventitia of the whole of the thoracic aorta in the form of firm, bluish and white plaques, resembling cartilage, running transversely, so that a general resemblance to the trachea was produced In his other cases less marked lesions were noted in the adventitia, sometimes only of microscopical size, but in all changes of the nature of granuloma formation, resembling Aschoff's bodies, were found The author thinks that the changes he describes are commonly to be found in the aorta if the microscope is used, but is not sure whether

similar appearances are to be found in other affections such as general septic infection Only further study can clear up this point

A. G. NICHOLLS

New Clinical Aspects of Alcoholism, Richardson, J. L., and Blankenhorn M. A., *Am J M Sc*, 1928, clxxvi, 168

This paper is based on 198 cases of alcoholism treated at Lakeside Hospital, Cleveland, from 1921 to 1926 inclusive The cases of acute alcoholism showed a mild fever and transient albuminuria Acute injury of the kidney was never prominent in such cases before prohibition The average age of the 51 acute cases was forty-six, of these 41 were men and 5 were women Unusual and bizarre symptoms noted were apparently due to alcohol plus other poisons

The average age of the 24 cases of chronic alcoholics was 50 years Eight chronic alcoholics entered hospital with the complaint of nervousness, they were apprehensive, shaking, and appeared on the verge of delirium tremens but none had delirium This picture is apparently common in the chronic alcoholism of to-day Only 5 cases could be definitely called delirium tremens During the five years preceding prohibition there were 20 of these The daily tippler has given way to an individual who indulges in daily sprints

The patients with neuritis complained of weakness, pain and paræsthesia The period of disability was short

There were 14 cases of cirrhosis of the liver whose ages were between 48 and 69 years All but one case had a history of taking alcohol daily The period it was used varied from 8 to 40 years Ascites was present in 50 per cent of the cases

LILLIAN A. CHASE

Drunkenness. A Quantitative Study of Acute Alcoholic Intoxication Bogen, E, *Am J Med Sc*, 1928, clxxvi, 153

Until recent times it has been the state of drunkenness, and not the act of drinking, that has been condemned as reprehensible. The higher courts of Ohio have held that a man cannot be considered intoxicated even though the odour of alcohol on the breath, a flushed face and a disposition to talk loudly and freely be shown, unless it is further shown that he has lost either the control of the faculties or of the muscles of locomotion. In this study no person has been diagnosed as suffering from acute alcoholism in the absence of convincing evidence of loss of control and co-ordination of the muscles of speech and locomotion, in addition to mental alterations and the odour and symptoms of alcoholic imbibition.

The differential diagnosis of drunkenness—The courts have repeatedly held that the recognition of drunkenness is a matter of simple observation on which anyone may testify without any claim to expert ability or special training. Not a few of the symptoms may be produced by other causes besides the drinking of alcohol. Thyrotoxicosis or hypoglycemia resulting from hyperinsulinism, with dilated pupils, tremors, flushed face and tachycardia, and other conditions affecting the eyes, mouth or limbs may produce symptoms simulating those of acute alcoholic intoxication. So also may lesions of the central nervous system.

General survey of the material—Five hundred cases of suspected acute alcoholism were studied. The beverages used varied widely. The manifestations presented by the patients after any of these liquors were so uniformly related to the ethyl alcoholic content of the urine or breath that no attempt was made to classify them on the basis of the liquor responsible. No case of especially toxic effects from the presence of impurities or denaturing substances was noted, such as blindness from methyl alcohol, albuminuria from metallic poisons or hæmatemesis from gastric irritants. Two deaths were directly due to alcohol.

The diagnosis of acute alcoholic intoxication was made in more than two-thirds of the cases on the basis of clinical findings alone. The odour of alcohol on the breath was noted in more than 75 per cent of them. More than one-third of these had flushed face and dilated pupils. Noticeably contracted pupils were found in more than 12 per cent. Unequal pupils were found in 12 patients but cleared up as they became sober. Nearly one-fifth of the patients were in actual coma on admission. Many were stuporous, but in some instances this was due to causes other than alcohol. In addition to seven patients with actual or incipient delirium tremens many were

nervous, quavering, tremulous or restless, there was one case of convulsions. Vomiting was frequent, loss of control of urinary and anal sphincters was encountered, but a number had to be catheterized. Conjunctivitis, cyanosis, hicough, and double vision were rarely noted. Albuminuria was found six times despite the statement that alcohol converts a positive to a negative reaction.

Correlation of the data—There is a relationship between the concentration of alcohol in the urine and the degree of intoxication of the subject. Not one of the 33 patients having less than 1 mgm of alcohol in 1 cc of urine was found to be intoxicated, more than one-half of those having 1 to 2 mgm, three-quarters of those having 2 to 4 mgm, and nearly all having more than 4 mgm of alcohol in 1 cc of urine were so diagnosed.

The concentration of alcohol in the urine can not be accepted as an absolutely accurate indication of the alcoholic concentration in the tissues unless we know exactly the time period during which it was secreted. This objection has been met by having the subject void on admission and again fifteen minutes later and taking the latter sample as representing the concentration of alcohol in the patient during this interval.

The concentration of alcohol in the breath offers a satisfactory substitute for alcohol in urine when a specimen is not available. The technique of estimating alcohol in the breath is described.

Relationship of urinary alcohol to the amount imbibed—Observations under controlled conditions allowed the workers to follow the changes in the alcoholic content of the urine at different intervals following the ingestion of known amounts of alcohol. The period of highest concentration came earlier in a subject who was more accustomed to such beverages, the concentration rose more rapidly following the taking of absolute alcohol than after beer.

The alcoholic content of the spinal fluid—This was determined in twenty cases. It was very close to that of the urine. Increased pressure was found in cases containing more than 3 mgm per cc. The patients were often roused considerably and sometimes completely after the puncture.

Conclusion—The examination of persons to determine the state of intoxication should in every instance include some such quantitative estimation of the amount of alcohol in the body fluids. The quantitative tests do not supersede or replace all of the other clinical evidence, but they constitute the most reliable single factor in arriving at a correct diagnosis of acute alcoholic intoxication of a patient.

Tetanus Following Smallpox and its Prevention
Armstrong, C, *U S Pub Health Rep*, 1927, 31, 3061

For a number of years the United States Public Health Service have been interested in the subject of post-vaccination tetanus. Their investigations showed that in one instance the infection was due to the presence of *B tetani* on the bone point scarifiers used and in another the organism was found in the bunion pads used as a dressing. Apart from these two sources however, it has never yet been shown that the tetanus organism was present in any other commercial dressings, needles or capillary tubes. Particularly careful tests were carried out on commercial vaccine but it was shown to be sterile in every instance. The only possible means by which these occasional cases of tetanus can occur after vaccination therefore are the presence of the organism at the site of vaccination or its subsequent introduction. The paper under review discusses the conditions which are most likely to favour the development of tetanus, granting that the infection in some way or other gains access to the site of inoculation.

First of all, an analysis was made of the various cases of tetanus throughout a number of years, and the following facts were established: (a) a dressing or shield was used in every case, throughout all or part of the development of the vaccination, (b) in most instances the vaccination lesion was a large one, (c) in all cases the tetanus followed primary "takes", which were usually severe.

A comment is then made on the malignant influence of shields and dressings, showing how these tend to favour stasis of blood and lymph, with development of exudate, the moisture from which macerates the skin and promotes development of bacteria. The writer observes in passing that he has never seen any reference to tetanus complicating smallpox, and yet this presents multiple lesions similar to those of vaccination, but dressings of course are absent.

Experimental evidence is then brought forward to show that in monkeys and rabbits vaccinated with virus artificially contaminated with tetanus, the development of tetanus was markedly advanced by the use of shields and dressings.

As a result of these investigations the following suggestions are made as regards the best method of vaccination: (1) No local covering should be employed. If an open lesion develops a few layers of gauze may be pinned inside the sleeve, or loosely applied to the arm, with the adhesive straps as far from the vaccination site as possible.

2 The insertion of the virus should be in a small area, never more than $\frac{1}{8}$ inch in diameter. The method recommended is that of a number of pricks through the virus, not driving the

needle directly in but pressing its side against the skin, wiping off the virus immediately after. The skin should not be rubbed with antiseptics too vigorously beforehand. Acetone is recommended amongst other solutions. The site is of some importance, since in those who are up and about the leg is obviously more exposed to infection than the arm. The age is also an important consideration, since not only does the vaccination usually run a milder course in infants, but there is less danger of contamination from their confinement, with its lessened opportunity of infection. The greater activity of boys bringing them in contact with an environment more likely to contain tetanus organisms may account for the greater incidence of post-vaccinal tetanus amongst them than in girls.

H E MACDELMOT

Hypertension and Diabetes Kramer, D W
Am J M Sc, 1928, clxxvi, 23

The combination of hyperglycæmia and hypertension occurs frequently. What is the relation between them? Three theories have been given. First, increased activity of the chromaffin system, second, that the hypertension produces an arteriosclerosis which involves the pancreas, third, that the hypertension and hyperglycæmia are both results of faulty metabolism. The author takes a systolic pressure of 150 mm as a basis of hypertension. In this study of 500 consecutive cases of diabetes 195 patients (39 per cent) showed a blood pressure of 150 mm or above.

The presence of hypertension may be attributed to various factors, namely, errors of diet (metabolic disturbances), mental unrest (prolonged mental strain), wear and tear, endocrine disturbances, infections and nephritic conditions.

The causes of diabetes are neurogenic, endocrine disturbances, hereditary influences, race, infections, errors of diet, and obesity. The similarity of the causes is striking. The tendency for diabetes to occur late in life also applies to hypertension. This was evident in the series of 500 diabetics, of whom 36.2 per cent were in the sixth decade, in the non-diabetic hypertensives 40 per cent were in the sixth decade.

Individuals with persistent hypertension of the non-nephritic type may in time develop diabetes. It is unlikely that diabetes, through its hyperglycæmia, produces hypertension.

LILLIAN A CHASE

SURGERY

Causal Factors in the Surgical Mortality of Exophthalmic Goitre Pemberton, J D, *N Y State J M*, 1928, xxviii, 256

Post-operative hyperthyroid crisis was former-

ly the most baffling problem in the treatment of goitre. This hyperthyroid crisis had a symptomatology of extreme tachycardia, high fever, nausea and vomiting, restlessness, great prostration, mental stimulation, delirium and death within twenty-four hours. No anatomical cause for death could be discovered and no measure proved effectual in checking the progress of the reaction. The only hope of treatment lay in prevention and efforts were directed at means of reducing the intensity of this reaction. This attempt at prevention led to minor surgical procedures, such as ligation, and all other efforts to improve the patient's condition.

The potential factors in the surgical mortality of exophthalmic goitre can be divided into three groups: (1) accidents, often the result of technical error, (2) acute post-operative crises, (3) the debility of the patient, the result of long-continued hyperthyroidism. By improvement in operative technique, surgical accidents have been reduced to a minimum.

The administration of iodine to exophthalmic goitre patients under preparation for surgery has resulted in a tremendous step in progress and the author believes that history will record as the three greatest influences in the development of surgery of exophthalmic goitre, the discovery of aseptic surgery, the discovery of anaesthesia, and the use of iodine in the pre-operative preparation.

There can be no standardization of the pre-operative preparation and the method must be adapted to the individual patient, but the more toxic the patient the greater is the care and time needed in the pre-operative preparation. However, three measures are essential for all patients: iodine, rest, and a high-calorie diet. General debility as an additional hazard must not be overlooked and this occurs in two distinct groups of cases: first, those debilitated as a result of a recent crisis, and second, those cases of long duration resulting in visceral degenerative changes. It is important to establish the patient's confidence. The second consideration is the anaesthetic, either local or a combination of local and general. The most common technical complications in the surgical treatment of goitre are injury to the recurrent laryngeal nerve and post-operative hæmorrhage.

The Diagnosis of New Growths of the Colon

Kahn, Maurice, *Am J Surg*, April, 1928

Thirty-five per cent of colonic cancer cases are inoperable when they reach the surgeon. Eighty-five per cent of the remaining 65 per cent reach the operating table too late for cure. Ten per cent of the total number encountered are alive 5 years later, even with the most extensive operation. The benign tumours consist of adenoma, lipoma, fibroma, myoma, papilloma,

and angioma. The malignant tumours are sarcoma and carcinoma. Sarcoma is rare, while carcinoma is the most common of all colonic tumours.

Constipation, or constipation alternating with diarrhoea, should occur only in those cases where the tumour partially obstructs the lumen of the gut. Diarrhoea alone would be more likely to occur in the irritating type of growth, not in the obstructive type. Blood-stained stools may arise from any vascular tumour, ulceration, or from marked congestion. Belching is a constant symptom of various abdominal conditions so has little differential value, but it may be an outstanding symptom of rectal disease.

Nausea and vomiting occur in 50 per cent of the cases. Cramp-like pain is due to a narrowing of the lumen and occurs in 75 per cent. It is a valuable sign of obstruction, but a milder sort of pain, more of a discomfort which comes and goes, is frequently found in the smaller tumours and should lead to thorough investigation. Meteorism, cachexia, and visible peristalsis are usually late manifestations, as is also anaemia. It is always well to think of the possibility of cancer in an otherwise unexplained secondary anaemia. Tenesmus is apt to be marked in low-lying growths.

Tuberculosis of the caecum may simulate carcinoma very closely. If it is secondary to tuberculosis of the lung, an error in diagnosis is not likely, but, if it is primary, differentiation may not be possible, though it is more apt to occur in the young, whereas cancer occurs usually after forty. Diverticulitis may occur anywhere in the alimentary canal, but it is usually in the left colon.

Intussusception occurs usually in children, but when it occurs in the adult it is frequently caused by a new growth, which may be pedicled or sessile. Therefore, in intussusception in an adult, it is always wise to make a diligent search for a tumour.

Many patients consult their physician or surgeon for the first time during the onset of obstruction, or partial obstruction, and many patients make light of pre-existing minor symptoms. When a patient of the cancer age shows unusual disturbance of bowel function lasting more than a few days it should arouse the attending physician's curiosity enough to prompt an investigation. There is no excuse for overlooking tumours of the rectum.

An Efficient Treatment for Varicose Ulcers

Marconci, E. E., *Arch of Derm & Syph*, 1928, xviii, 2

From studies by Lowenfeld in 1924 it was found that there were no specific organisms in varicose ulcers of the leg, although staphylococci and streptococci were the forms most commonly

found. With the reduction in the number of bacteria by treatment there was progressive healing. The bacteria were always most plentiful on the surface of the tissues. Apparently, as in normal healing, the granulation tissue prevents the bacteria from penetrating deeply.

In view of the rich and varied flora of these ulcers as shown by Lowenfeld, it occurred to the writer that general sterilization of the wound would be the best method of attack. He first tried an ointment of 1 per cent neoarsphenamine, and obtained highly gratifying results. This ointment was applied overnight, once daily. This treatment is painful, so the following ointment was evolved, neoarsphenamine, 0.3 grm, ethylaminobenzoate, 2 grm, white petrolatum, 30 grm. After this had been applied once, a 10 per cent bismuth subgallate ointment was used for a few days.

The results obtained from this treatment were highly satisfactory, the ulcers becoming clean, and healing rapidly and permanently.

Expulsion of Tooth Root Through Nose via Antrum Van Coller, F. A., *J. M. Ass. S. Africa*, 1928, II, 414

The author regards this case as one rare enough to deserve record. A lad had a tooth extracted. Apparently extraction had been difficult, and it was feared that one of the roots had been snapped off and driven into the antrum. Later, the patient complained of a bad smell in the nose and a slight discharge from the root socket. A subsequent radiogram revealed a small shadow in the upper part of the antrum. He was continually using his handkerchief and blowing his nose. One day, feeling an unusual irritation in the nose he had blown it violently, and, feeling something sharp come away, he had looked in his handkerchief and found the root. It had been in the antrum sixteen months.

A. G. NICHOLLS

The Application of Pathology to Surgical Problems Codman, E. A., *New England J. Med.*, 1928, cxcviii, 332

"Although pathological opinion in individual cases is often the most important which the patient receives in the hospital, and is therefore a necessity for efficient treatment, a far more important function of the pathologist is his ability to teach. Every man who practices medicine in any of its branches needs a sound training in pathology, but none more so than the surgeon. It is therefore a surgical problem to see that the supply of pathologists is kept up. So far as our influence on medical faculties and hospital boards goes we should advocate adequate budgets for the pathological departments,

and reiterate that the supposed advances in surgery of recent years are largely due to the pathologists and that our own daily work would be less effective if we had not had training in pathology. I think we older men can also do something in advising our assistants that a year or two in a laboratory where gross pathology can be studied and correlated with the histology will surely make a better surgeon. We surgeons must also accent our demand for a clinical tissue pathologist as opposed to one from the widening subdivisions of pathology which are now engaging attention, as serology, immunology, etc. If one looks over the journals of pathology, few articles on gross or minute pathology are seen. Practically, the tissue pathologist is disappearing and it is a very important problem for surgeons to make an attractive place for him. Perhaps the answer will be to isolate the bulk of the surgery of malignant disease into a specialty and let the surgeons do their own microscopy." (Abstracted in the *Bulletin*, Association of American Medical Colleges, July, 1928)

OBSTETRICS AND GYNÆCOLOGY

The Hormone Test for Pregnancy Siddal, A. C., *J. Am. M. Ass.*, 1928, xci, 779

At the beginning of this year Dr. Siddal published a preliminary report on a suggested test for pregnancy, based upon a study of forty-five cases. The results of his investigation were epitomized in the *Canadian Medical Association Journal* (1928, xix, 373) as they seemed promising. Now, the author gives his investigations on ninety-seven additional cases, which in general confirm his previous observations.

In brief the test (improved) consists in the injection of the blood serum of pregnant women into sexually immature female mice weighing less than 18 gm. In this case enlargement of the uterus follows, or, the test can be applied to sexually mature female mice, when a striking enlargement of the ovaries results. The total mouse weight divided by the weight of the uterus plus ovaries gives a ratio that serves as an index. If the ratio is above 400 the test is considered negative for pregnancy, if below positive. Excluding three cases for technical reasons, there were only six erroneous results in his total of 142 cases. The specific agent is probably a hormone. This test is reliable early and late in pregnancy and the author thinks it is of practical value. The test can also be used for the qualitative determination of the potency of commercial liquid extracts of ovary, placenta, and probably of the anterior lobe of the pituitary body.

PÆDIATRICS

Factors in the Decay of Teeth Kappes, L O,
Am J Dis Child, 1928, xxxvi, 2

It has been observed that the incidence of dental caries in the northern States is rather high, a fact borne out by the results of inspection of the school children of Rochester, Minn. In order to determine the possible reasons for this an investigation amongst these school children was instituted. Two groups of 25 each were studied, one group possessing good teeth and the other showing marked dental caries.

The procedure was to obtain all the details possible about the children's diet from birth, the condition and care of the teeth, the time of eruption, the amount of outdoor play, general health and past illnesses. The health of the mother was also inquired into, her diet and health during pregnancy, the amount of exercise taken and exposure to sunshine, and dental trouble during the period. The condition of the teeth of both parents was obtained when possible.

Much information was collected and analyzed, but the net conclusion of the investigation was "not as striking as one would expect." The only factor that seems to be of definite etiological significance in preventing decay of teeth is a diet composed of fruit and vegetables.

H E MACDERMOT

PATHOLOGY

Syphilis et Maladie de Hodgkin (Syphilis and Hodgkin's Disease) Langeron, L, *Bull et mém Soc Med d Hôp d Paris*, Dec 15, 1927, li, 1619

Following a personal observation, the author takes up the question of a possible relationship between Hodgkin's disease and syphilis.

His patient was a man, aged forty-five years, with a maculo-papular rash and fluctuating swellings on the nose and tibia, who was cured of his affection by specific treatment. Two months afterwards he developed a generalized adenopathy with eosinophilia. Death occurred one month later. The autopsy showed multiple enlarged glands with splenomegaly. The histological and parasitological studies in the case were negative for syphilis, but characteristic for lymphogranulomatosis. Nothing in the study of the case indicated that the Hodgkin's disease present differed in any way from other cases. Anti-syphilitic treatment had been ineffective so far as the lymphogranulomatosis was concerned. He concludes that syphilis is not one of the etiological factors in the anatomico-clinical syndrome known as Hodgkin's disease.

He supports his conclusion, further, by the following considerations—

1 A history of syphilis is not found more

often in Hodgkin's cases than in those of other diseases taken at large.

2 The lesions in Hodgkin's disease bear no resemblance to those in syphilis.

3 The syphilitic adenopathy does not present the same clinical picture as that of Hodgkin's disease.

4 In only one case, that of Loewenbach, was specific treatment followed by success.

5 The Wassermann reaction only indicates the nature of the soil, and should not prejudice the occurrence of another subsequent affection.

6 The observation of Proescher and Winter, who found spirochaetes in the lesions of lymphogranulomatosis, remains isolated.

A G NICHOLLS

THERAPEUTICS

The Response of Chronic Nephrosis to Parathyroid and Thyroid Medication Lewis D S, and Sernei, W de M, *Ann Int Med*, 1928, ii, No 1, 66

This is a carefully written review of modern ideas concerning nephrosis. The writers conclude that lipoid or chronic nephrosis is of rare occurrence in pure form, but in coincidence with other chronic nephritides it will probably be recognized more frequently with careful study. Seven fully identified cases have been recognized at the Medical Clinic of the Royal Victoria Hospital, Montreal, within the last two years. Extended chemical studies are necessary to recognize the condition, but it should be suspected when there has been an insidious onset, a long continued oedema, copious albuminuria and marked pallor, without evidence of cardio-renal involvement. A milkv plasma, noted a century ago by Bright, is an added diagnostic feature.

The authors give details of four cases of chronic nephrosis, one only being of the pure form. The first case responded strikingly to parathyroid medication, the second and third showing no response to it. The second case became oedema-free after all treatment had been stopped; in the third case the oedema subsided after massive doses of desiccated thyroid gland. In the fourth case there was a rapid advance of the disease after thyroid medication. In no instance was the albuminuria affected by the treatment.

It was only the case of pure nephrosis therefore in which there was a response to parathyroid extract. It is this pure type only in which much improvement may be looked for. In the mixed type of case there is usually a gradual progress of the associated nephritis.

H E MACDERMOT

Use of Subcutaneous Injections of Oxygen Kirk, T S, *Brit. M J*, 1928, ii, 185

Dr Kirk has collected a number of cases of

pneumonia in which subcutaneous administration of oxygen has been successfully practised. The good effects are said to be due to neutralization of the toxæmia with perhaps some action on the organisms themselves. There was a uniform hastening of the crisis following its administration.

Its value, however, is apparent in other cases in which anoxæmia is present, such as post-anæsthetic sickness, or scalds and burns. In the latter condition Dr. Kirk has had extensive experience of the valuable results from oxygen, especially if given early.

The gas is injected straight from the cylinder through rubber tubing and a fine needle. There is no need for heating or filtering the gas. A convenient place for giving it is below and outside the breast. The quantity to be given need not be measured very closely. Experience showed that if enough gas was injected to inflate the skin over an area equal to the size of the palms of two hands, the amount would be in the neighbourhood of 200 c.c., which is a safe initial dose. Much larger amounts can be safely given. In bad cases it is best to give about 400 c.c. at first and repeat in six hours if most of it has been absorbed. It can be given as easily and as quickly as serum, and is less painful. No ill effects, either locally or generally, have been encountered in an experience of about 200 cases.

H. E. MACDERMOT

Prone Pressure Method in Electric Shock Report by an Engineering Committee on Electric Shock *J Indust Hyg*, 1928, x, 117

The use of the Schafer prone method in resuscitation from electric shock and recognition of its value has only occurred within the last few years. Various public utility bodies in Canada and the United States have offered medals as rewards in instances of successful resuscitation, the Canadian Electrical Association medal being awarded also for resuscitation by means other than the Schafer method. It is of interest to know that the medal used for preparing the Canadian Association medals came from the wire forming the first high tension line in the British Empire (that of the North Shore

Power Company between St. Nicks and Three Rivers).

The report under review includes a total of 265 cases of electric shock. Of these, 200 (75 per cent) were resuscitated by the prone pressure method, and the remainder died in spite of attempted resuscitation. Analysis of the 200 successful cases reveals several points of interest. (1) The greater percentage of successful cases was amongst those who had received the higher voltages. (2) There was a slightly higher percentage of success amongst those who fell clear of the contact than amongst those who were removed by other means—78 per cent as against 71 per cent. (3) A considerably higher percentage of success was obtained amongst those on whom resuscitation was carried out within the first three minutes of the shock than when a longer interval had elapsed (78 per cent as against 67 per cent). (4) The average length of time necessary for resuscitation was found to be from 15 to 20 minutes, independent of the voltage. Several cases, however, required much longer periods, varying from one to two and a half hours, with one case requiring eight hours.

It is evident therefore that the duration of contact with the current is an important factor in the prognosis and that attempts at revival must be begun at the very earliest possible moment.

As a result of their wide experience the public utilities in the United States and Canada have unanimously condemned mechanical devices for respiration such as the pulmotor, lungmotor, and other similar devices. The Commission states that these devices are "paradoxically enough" only used by the companies when demanded by the attending physician.

The Schafer method is fatiguing to the operator and may be dangerous to the patient if not properly carried out. It is often necessary to change the operator from time to time. It is important to keep the patient warm and to insist on his remaining quiet for some time after revival. A brief return of natural respiration is not necessarily an indication for stopping the resuscitation. Above all it should not be stopped until it is absolutely certain that there is no hope of revival.

H. E. MACDERMOT

Life certainly is a struggle for existence. All organisms are forced to protect themselves against the injurious agencies in their environment. Life is a perpetual adjustment and re-adjustment of the individual to its environment. All adjustments may not be ultimately beneficial to the species though they may confer an advantage upon the individuals of a particular generation. For example, if one method of protection

against a particular enemy is completely successful, other methods become unnecessary, and since the organism is no longer selected with reference to these, they may drop out of the equipment of the species and be seriously missed when later in the history of the species they are demanded.—F. A. E. Crew, *Edinb M J*, 1928, xxxv, 401.

Obituaries

Dr Robert Johnstone Blanchard passed away suddenly in Winnipeg on September 10th. He was born in Tiuro, NS, in 1853, and was educated at the University of Edinburgh (MB, 1877). He acquired there not only an excellent professional training but also that philosophical spirit that dominates the Scottish nation. His active life was spent in Manitoba and he attained the highest standing among his confreres, and the respect and confidence of his large clientele. He was one of the Incorporators of the Manitoba Medical College, and for many years as Professor of Surgery was a capable and inspiring teacher. Surgeon in chief for the Western Division of the Canadian Pacific Railway, he took a prominent part in the development of that system during its early years. As President of the Canadian Medical Association in 1909 he aided in the progress of our profession in its scientific, business, and social aspects. During the war he spent two years in France as Commanding Officer of No. 3 Canadian Casualty Clearing Station. In 1921 the University of Manitoba recognized his scholarship and professional attainments by conferring on him the degree of LL.D. Every one who knew him will carry in thankful recognition the image of the perfect gentleman. To have known Dr. Blanchard well was an education in honesty, simplicity and sincerity. H. H. CHOWN

AN APPRECIATION

My recollections of Dr. Blanchard go back for sixty-five years. We were boys together at school in Tiuro, but he was several years younger than I. He was a clever boy, but his chief distinction was his ability as a reciter. At the public examinations, or other special occasions, he was in great demand. He had the gift when declaiming a parody, or some other mirth-provoking piece of prose or verse, of preserving the most dignified gravity of face and demeanour while his audience rocked with uncontrollable laughter.

But it was eight or ten years later, when he and I were beginning our medical studies in Dalhousie University, that we became really acquainted and formed a friendship which has been one of the happiest conditions of my life. This friendship was very close and intimate when we roomed together during our years of study in Edinburgh University.

He was a keen and diligent student, distinguishing himself especially in anatomy and physiology. He never "crammed" but he was not a superficial reader, and when faced with conflicting opinions, *Nullius in verba* he strove to ascertain the fundamental facts and to theorize for himself. He gave much of his time to practical work, especially as a dresser in the surgical wards.

We graduated on the same day, August 1, 1877, and soon after he was appointed resident medical officer at the Craiglockhart Poor House Infirmary near Edinburgh. In this first appointment he showed what manner of man he was to be, for he attracted the attention of the Director by his tireless devotion to his duties and his thoughtfulness and sympathy for the tired, sad, hapless people who were his charge, particularly the old men and women and the cripples.

After some weeks he became resident surgeon in the Stirling Infirmary, one of the best of the best "provincial" hospitals in Scotland. Here he was a very great favourite, not only with the patients who were touched by his kindness and gentleness, but with the visiting staff who soon recognized his ability and trustworthiness. One of my happiest recollections is a visit of two or three days with him in this hospital. He held this position for a year and resigned when he returned

to his home in Nova Scotia. He and I came out together in December, 1878. After he had spent some weeks with his friends, he secured a position as one of the doctors in the service of the Canadian Pacific Railway, then

Dr. Robert Johnstone Blanchard

constructing the line beyond the Great Lakes, and for two years he knew the hardships and toils of practice among the woods, lakes, rocks and rivers of the famous Section B. Here again he gained a reputation, not only by his success in the surgical cases under his care, but by the energy and endurance displayed in making his way to the injured. If a "trolley" was not available he would tramp for miles through the bush, carrying his surgical outfit, or paddle a canoe, or in winter walk on snow shoes through woods or on the ice. By day or night, in rain or blizzard, he would find his way to the scene of the accident. There are old men now who love to tell of his hardiness and endurance as well as his skill. When he left this position to settle in Winnipeg the contractors and men working on Section B presented him with a fine set of surgical instruments and an engraved address testifying to their regard for him.

His connection with the Canadian Pacific Railway did not terminate when he left Section B, for he was for many years medical advisor and chief surgeon on the Western Division of the road. He became one of the best known and respected medical men of the west. He took a keen interest in medical education and was one of the founders of the Manitoba Medical College. He was President of the Canadian Medical Association in 1909. In the late war he commanded No. 3 COS,

and that unit was a model of organization and efficiency. I remember being told by the A.D.M.S. of that area that he took Colonel Blanchard up to Remy Siding and showed him a green field and said "There's your field," and that he was surprised and pleased at the rapidity with which the staff of No. 3 had set up their hospital.

A few days ago in Ottawa, I met Dr. Prowse and Dr. Thornton mutual friends of my own and Dr. Blanchard, and asked them for my old friend. I knew that some time ago he had had some disquieting symptoms but in the last letter I had from him he reported himself as much better. They both told me he was looking better. I said "All I want is that Bob and I should live to meet in Winnipeg in 1930, and hear the Third Listerian Oration." They said "Both of you look quite fit for that."

But he has gone, and a part of my life seems to have gone also.

JOHN STEWART

Dr. David James Evans. It is with much regret that we announce the sudden death on September 1st of Dr. D. J. Evans, formerly Associate Professor in Obstetrics in McGill University. Born in Montreal, May, 1868, he was the son of Mr. Edward Evans, who spent some years of his life as missionary in China. He received his early education at the Montreal High School and Lincoln College in Sorci, and after spending a year in the Faculty of Arts entered upon the study of medicine in McGill University from which he graduated in 1890. Shortly after graduating he received the appointment of resident physician in the Montreal Maternity Hospital, and at the end of this appointment he accepted the position of Superintendent of the Montreal General Hospital, made vacant by the resignation of the late Dr. R. C. Kirkpatrick. Much interested in the practice of midwifery he resigned from this position on the advice of friends, and went overseas to pursue special studies in France and Germany, and upon his return to Canada was offered the position of Demonstrator in Obstetrics in McGill University. This he accepted in 1895, and from this position rose to be Lecturer in Obstetrics in 1900 and Associate Professor of Obstetrics and Diseases of Children in 1912. During this period, besides numerous contributions to medical journals, he wrote for a Philadelphia firm a Student's Handbook of Obstetrics, which passed through two editions and was translated into one of the eastern languages.

For many years he was also one of the attending physicians at the Montreal Foundling and Baby Hospital, and always took a warm personal interest in both its medical and financial success. He rarely missed attendance at the monthly meetings of the Board of Governors.

Dr. Evans made many friends during his college days. He had deeply religious convictions and took an active part in the Young Men's Christian Association of this city, and for one year acted as its President. During the early part of his career he had looked forward to entering upon the foreign missionary field, but with opportunities opening in Montreal this thought was given up.

Although keenly in favour of the more robust and athletic side of student life, all through his life, yet he never took an active part in college sports. A tinge of fatalism in his mentality held him to the conviction that he would never pass his sixtieth year, and appears to have influenced his choice of recreation even in youth.

Eight years ago he retired from active practice, and after two years' residence abroad returned to America, taking up his residence in Boston and making his home in Dover, Mass., during the summer months. He was appointed by the overseers as a visitor at Harvard Medical School, and in many ways continued his active interest in medical matters. He was a trustee of the Old Ladies' Home, a member of the St. Botolph

Club, Norfolk Hunt, Dodham Country and the Pellet Club of Dover, as well as of the Mount Royal Club of Montreal.

Dr. Evans was twice married, his first wife, Miss Mary Franklin of East Orange, N. J., died with him. His second wife, Miss Rosalind Allen of Boston, preceded him with two children.

H. D. HAMMILL

Dr. David James Evans

AN APPRECIATION

I have learned with deep regret of the recent death of Dr. David J. Evans, which occurred in the United States. While residing in Montreal he was one of the most distinguished members of our medical profession.

It is several years ago that I met him for the first time, he was then on the teaching staff of McGill in connection with obstetrics and diseases of children. We sat together on the Pure Milk League Commission with Prof. A. D. Blackader, Dr. Milton Hersey, Dr. S. Boucher and the late Dr. I. Cormier, Professor of Pathology at the University of Montreal. We were all very deeply interested in the reorganization of the Montreal milk supply, and had many meetings at Dr. Evans' residence on Dorchester Street West. Our proceedings, some way or another, attracted the attention of Lord Atholstan (then Sir Hugh Graham) who subscribed all the money we needed to make a close inspection of some of the milk producing districts surrounding Montreal. We were then able to obtain the services of the late S. M. Barre, a man of experience as special inspector. Dr. Evans was the most active member of this Milk Commission and I am glad to say that his good advice, together with the educational campaign instituted by our inspector did a great deal towards the improvement of our milk supply.

Later on, during the great influenza epidemic, when a consulting hygienic committee met every day, presided

Dr Tyrrell was very active in church work, in connection with St Anne's Anglican church of which he was a member. He is survived by his widow, two sons and one daughter, and by three brothers.

Dr William Wilkinson died in Edmonton, Alberta, on August 18th. He had just received an appointment as surgeon to the Royal Canadian Mounted Police and was proceeding to Herschel Island in the Arctic when he was stricken.

Dr Wilkinson was the son of the late W. S. Wilkinson of Woodstock. He is survived by his widow and one son, and by his mother and a sister. Interment was in Avon.

Dr William John Smith, one of the most honoured citizens of Brampton, Ont., died at St. Michael's Hos-

pital there on September 17th, in the 81st year of his age. He had met with an accident on September 1st, when his automobile was struck by a truck at the corner of Nelson and Park Streets. The injuries were eventually proved fatal.

Dr. Smith was born at Ripley, the son of the late Robert Smith. He graduated in medicine at the University of London and then took a post graduate course for two years in London, England. He first engaged in practice at the place of his birth, in partnership with Dr. J. Vanderlip but removed to Brampton about nine years ago. Ever ready to answer the call of a patient, conscientious in his work, he endeared himself to the people in his town.

Dr. Smith is survived by his wife, formerly Miss Priscilla May Rogers, and two small children, and by his aged mother at Ripley, five brothers and three sisters.

GREAT BRITAIN

The fourteenth annual conference of the National Association for the Prevention of Tuberculosis, which is to be held in the British Medical Association House, Tavistock Square, London, on October 15th and 16th, will be attended by a number of Canadian medical officers who are visiting Europe to study tuberculosis work. Sir Arthur Stanley will preside, and the principal speakers in the first day's discussion, on "The occurrence of tuberculosis among primitive peoples," will include Dr. R. C. Ferguson (Saskatchewan), Dr. Vassal (Annam), and Professor S. Lyle Cummins. The subject for the second day's proceedings will be "The principles underlying a scheme of anti-tuberculosis measures in any country," and the opening speakers will be Sir Robert Philip, Dr. Howard Holbrook (Canada), and Dr. G. Lissant Cox. A dinner in honour of the Canadian visitors will be given in the Savoy Hotel on the first day of the conference. The proceedings are open to all persons interested in tuberculosis. Full information may be had from the secretary of the Association, 1, Gordon Square, London, W.C.1. Recently the association announced the publication of a new series of posters designed to assist organizations and individuals in anti-tuberculosis work. These posters are eminently suitable for display in schools, hospitals, and dispensaries, public buildings and workplaces, most are printed in colour. Each embodies either a simple, direct message of advice on preventive methods or an appeal for support in the general campaign. A number of the posters have been prepared in postcard form. Another educational activity is the creation of a caravan service with three motor vehicles, each carrying a medical practitioner as lecturer, with a cinema, supplies of films, posters, charts, photographs, and other material for a small tuberculosis exhibition. These units are placed at the services of local authorities, etc., throughout Britain, and requests for co-operation will be welcomed. A leaflet illustrating the association's posters and giving details of the caravan educational service may be had on application to the address given above.

A public health congress and exhibition organized under the auspices of the various associations representing municipal and other local authorities, will be held in the Royal Agricultural Hall, London, in the week beginning on Monday, November 19th, when the opening ceremony will be performed by Mr. Neville Chamberlain, Minister of Health, who, as president of the congress, will afterwards address the delegates. The congress is designed to bring together all public health authorities

and all interested in social welfare work and the organizing committee, under the chairmanship of Sir Frederick Wilks, has secured the co-operation of many distinguished workers in the field of public health. Sir George Newman will give an address on the opening day on the purpose of the public health services. On the following day Sir Walter Fletcher will discuss research in public health, and Mr. C. Hubert Bond will deal with local organization for the prevention and treatment of mental disorders. On Friday, November 23rd, Dr. W. M. Willoughby, medical officer of health for the City of London, will give an address on food protection, and on the same day Mr. R. H. P. Orde, of the British Red Cross Society, will speak on the construction and equipment of hospitals. Housing, the smoke problem, milk supply, water supply, sewage, and town cleansing will also be discussed.

The Second International Conference on Light and Heat in Medicine, Surgery and Public Health will be held at the University of London, S.W.7, on October 29th, 30th and 31st, and November 1st.

Lord Haldane

"The death of Viscount Haldane, O.M., F.R.S., will recall to some of our readers that this distinguished statesman, lawyer, and philosopher was a nephew of Sir John Burdon Sanderson, M.D., F.R.S., Regius Professor of Medicine at Oxford from 1895 to 1905, and eminent alike as experimental physiologist and pathologist, and a brother of Dr. J. S. Haldane, F.R.S., of Oxford, many of whose addresses on the physiology of respiration and other subjects have appeared in these pages. Lord Haldane's personal claim to remembrance by our profession rests on his work as Secretary of State for War between 1906 and 1912. In the words of Sir Alfred Keogh, he was one of the two state-men in latter days (that is, since Lord Herbert of Lea left the War Office in 1860) who understood the Army Medical Department. The Territorial Service set up by Lord Haldane enabled the officers of the R.A.M.C. to come into organic union with their brethren of the civilian profession before the outbreak of war."—*Brit. M. J.*

Sir Thomas Holland, noted geologist and a rector of the Imperial College of Science, London, was elected president of the British Association for the Advancement of Science on September 12th. He has been connected with the association for thirty years. He will serve as president during 1929.

Sir Thomas Henry Holland, KCSI, KCIE, FRS, President elect of the British Association, is an eminent geologist, sixty years of age, and a son of the late John Holland, of Springfield, Manitoba. He was born and educated in England, and has served as Director of the Geological Survey of India, 1903-9, Professor of Geology and Mineralogy, Manchester University, 1909-18, member of the Governor General's Council, India, 1920-21, and Rector of the Imperial College of Science and Technology since 1922.

Radcliffe Infirmary, Oxford

MR MORRIS'S GIFT OF £38,000 FOR EXTENSION

Mr W R Morris, the head of the firm of motor car manufacturers, has promised a gift of £38,000 for the extension of the Radcliffe Infirmary, Oxford. This was announced at the quarterly meeting of the Court of Governors. The gift will be used for the building of a new maternity home.

NOVA SCOTIA

Canadian physicians who served overseas during the war will be interested to learn of the marriage of Major General Cailleton Jones. The ceremony took place at Alassio on the twenty-eighth of July, the bride being Countess Mannini, of Italy. General Jones is a son of the late Honourable A G Jones, at one time Lieutenant Governor of Nova Scotia. After his graduation, General Jones practised medicine in Halifax until he became a member of the Permanent Army Medical Corps. He was very active in connection with all medical affairs and for several years was secretary of both the old Halifax Medical College, and of the local branch of the British Medical Association. He was always interested in military medicine, and gained distinction in the South African war. It will be remembered that during the late war he was not in favour with the then Minister of Militia, and despite the fact which is very generally acknowledged that he rendered excellent service under very difficult conditions, he was retired from office, but retained the confidence and esteem of a large percentage of medical officers who felt that he had not been justly treated.

The Honourable Dr W N Rehfuess, who was appointed to the Provincial Medical Board by the Nova Scotia Government, has resigned this appointment.

In a recent issue, reference was made to a dispute between the City Council of Sydney, and the Medical Board of the Sydney City Hospital, relative to the purchase of a new x-ray plant. The matter has since been amicably adjusted, and an order has been placed for a thoroughly modern and complete equipment.

Miss Bon, who has been superintendent of the Pictou Memorial Hospital for some years, and who took an active part in the campaign which resulted in the replacement of the old hospital by the fine new building known as the Sutherland Memorial Hospital, has, to the great regret of all interested in the institution, resigned the superintendency of the new hospital to accept a very responsible position in a hospital in the United States.

A legal case which was very interesting to members of the medical profession, was recently before the Court at Truro. Action was brought to appoint a guardian to a man who suffers from Huntington's chorea. Medical evidence was brought in by both sides, and it is pleasing to note that all the doctors agreed that the patient was competent to conduct his own affairs. There have been quite a number of cases of Huntington's chorea in Nova Scotia, more especially in Colchester County. All the patients have been descendants of a brother and sister who came to Nova Scotia from the border of France and Switzerland to escape the persecutions which followed the revocation of the Edict of Nantes. In each of six generations of descendants of this brother and sister there have been several cases of the disease. The disease has been transmitted only by

those who actually suffered from it, and those in each generation who escaped the malady have not passed the disease to any of their progeny.

The members of the Pictou County Branch of the Medical Society of Nova Scotia paid a notable tribute to two senior colleagues on August 15th, when they tendered a complimentary dinner to Drs Ewan Kennedy and John W MacKay, of New Glasgow. Both of these gentlemen have served long and worthily in the ranks of the profession, and have enjoyed well merited esteem and confidence amongst all classes of the community. It is pleasant that their excellent qualities of head and heart and hand should have been recognized while they are still active in the practice of medicine. A number of prominent men were present at the dinner and spoke of Drs Kennedy and MacKay in quite as generous terms as the medical man who recounted their virtues.

Dr A F Miller, Superintendent of the Nova Scotia Sanatorium at Kentville, was married to Miss Lily Proctor, of Halifax, on August 18th. Dr Miller is well known to tuberculosis workers throughout the continent who will feel a special interest in his matrimonial venture. The wedding ceremony took place in St Andrew's Church, Halifax.

Drs A F Miller, Superintendent of the Nova Scotia Sanatorium, P S Campbell, of the Provincial Department of Health, and T M Siemewicz, of the Massachusetts Halifax Health Commission, have been chosen to represent Nova Scotia on the educational tour of the British Isles and Continent, arranged by the Canadian Tuberculosis Association.

Plans have been prepared for a nurses' residence in connection with the Children's Hospital, Halifax, and it is expected that work on the new building will be commenced shortly.

W H HATTIE

The members of the profession will extend congratulations to Miss Margaret MacKay, daughter of our good confrere Dr H H MacKay of New Glasgow, upon obtaining a further scholarship which will entitle her to do post graduate work in physiology at Toronto and McGill Universities.

Dr Charles Spiro of New Glasgow, while motoring to Sydney on August 3rd, struck a horse with his car. The force of the impact was such as to throw his travelling companion, Mr James M Milne, so violently against the side of the car that he was unconscious for some twelve hours from concussion.

Here is our present list of registered practitioners who graduated fifty years or more ago —

Dr A J Cowie, Halifax, graduated in 1860, 68 years ago, Dr Geo E Buckley, Guisboro, graduated in 1867, 61 years ago, Dr D O Saunders, Bridgetown, graduated in 1869, 59 years ago, Dr H B Webster,

Kentville, graduated in 1870, 58 years ago, Dr Daniel McIntosh, Pugwash graduated in 1871, 57 years ago, Dr Finlay MacMillan, Sheet Harbor, graduated in 1872, 56 years ago, Dr A M Perrin, Yarmouth, graduated in 1873, 55 years ago, Dr Robinson Cox, Upper Stewiacke, graduated in 1875, 53 years ago, Dr J N Mack, Halifax graduated in 1875, 53 years ago, Dr S N Miller Middleton, graduated in 1875, 53 years ago, Dr Chas I Fox, Pubnico, graduated in 1876, 52 years ago, Dr Evan Kennedy, New Glasgow, graduated in 1876, 52 years ago, Dr J R Chute, Elderbank, graduated in 1877, 51 years ago, Dr J D Denmore, Port Clyde, graduated in 1877, 51 years ago, Dr John Stewart, Halifax, graduated in 1877, 51 years ago

The new Lord Nelson Hotel in Halifax will entertain as its first guests the members of the Medical Society of Nova Scotia and their friends from October 15th to 20th, inclusive. The entire hotel will be reserved for this purpose, for the first guests and the first convention. This is really a notable event for Halifax and Nova Scotia and the Medical Society may well be congratulated upon this honour. When conventions with headquarters at this hotel become matters of weekly or monthly occurrence we shall stand as pioneers. The hotel for that week belongs to the Medical Society of Nova Scotia and only their friends will be entertained there for that time. The entire registration including Halifax guests for luncheons and dinners should reach the three hundred mark.

S. L. WALKER

PRINCE EDWARD ISLAND

The Prince Edward Island extra mural course for August was held at the Prince Edward Island Hospital, Charlottetown, on the 15th ult. The speakers were Drs. F. H. MacKay, Ray Brow and Geo. Little, all of Montreal.

Dr MacKay's talk on anterior poliomyelitis was not only instructive but also very timely in view of the opinion he himself gave, namely, that there is some likelihood of another epidemic throughout America in the near future. He stressed the importance of early diagnosis, the use of convalescent serum in cases seen early, with galvanism and massage for the late stages. He urged upon practitioners the necessity of considering the disease as an acute infectious one, rather than relegating it to the awe inspiring realm of neurology.

Dr Little in his discussion of fractures about the ankle joint, and Dr Brow on cardiac arrhythmias, gave us much valuable information in a clear concise way.

The extra mural courses continue to be very much appreciated by the Prince Edward Island men. Physicians, particularly those isolated as we are from the medical centres, owe a debt of gratitude to the Canadian Medical Association for originating this far-sighted policy, and also to the busy men who come to it at considerable personal sacrifice. We assure them that these lectures are enabling us to do much better and from our point of view at least are very much worthwhile.

J. W. McKEE

NEW BRUNSWICK

Dr R. J. Collins and Mrs. Collins, Dr W. Wherrett and Mrs. Wherrett, and Dr H. A. Farris, of New Brunswick, are in Europe on the Sun Life Tour for Executives of Tuberculosis Institutions. Dr Farris reports a very excellent reception in England and in a recent letter especially mentioned the hospitality provided for the party by Sir Henry Gauvain.

The annual meeting of the New Brunswick Medical Society was held this year on September 19th at Fredericton. The late date was necessary to avoid confusion with the Canadian Medical Meeting at Charlottetown.

The Council of the New Brunswick College of Physicians and Surgeons met in Fredericton on the evening of September 18th. Present at the annual meeting were Dr Price, Moncton, Dr Barry, Dr Addy, and Dr S. H. McDonald, St. John, Dr G. Clowes Vanwart of Fredericton, and Dr Laporte of Edmundston. Their reports with those of the Registrar and Treasurer were presented at the general meeting the following morning.

Discussion arose concerning Workmen's Compensation affairs. The following committee was appointed to meet the Compensation Board: Dr J. M. Barry, chairman, Dr V. D. Davidson, Dr A. S. Kirkland, all of St. John. Communications were presented from the Medical Protective Association, and from the committee dealing with the formation of the Canadian College of Physicians and Surgeons. The latter scheme was endorsed with the provision that New Brunswick men be included in the nucleus of charter members.

The election of officers resulted as follows: President, Dr C. J. Veniot, Bathurst, First Vice-President, Dr D. W. Ross, Fredericton, Second Vice-President, Dr A. S. Kirkland, St. John, Treasurer, Dr V. D. Davidson, St. John, Secretary, Dr J. R. Nugent, St. John.

Dr B. W. L. Earle of Perth was elected to fill the vacancy on the Council caused by the death of Dr Rankine of Woodstock.

Dr E. T. Ryan of Saint John left last month to spend a year in London and Paris doing advanced work in urology.

A. STANLEY KIRKLAND

QUEBEC

The Director General of Studies at the University of Montreal, Dr. Telesphore Parizeau, reports that a very heavy number of foreign born students have registered at the faculty of medicine for the coming scholastic year.

Miss Adrienne Boulé, of Quebec City, a graduate of Laval University, is leaving for Natashquan to establish a medical dispensary which will be the first of its kind in the region. A hospital is also to be built there eventually.

Health conditions were fairly good in the city of Montreal during the two hot summer months, according to Dr. S. Boucher, city health officer. He pointed out that the few cases of typhoid reported had been contracted in the country. He repeated his warning of the early summer regarding the drinking water and milk in the country. Measles had been nearly wiped out and there were no deaths from this cause during the month of August. Dr. Boucher summed up by saying that the proportion of deaths from various contagious diseases, except tuberculosis, is low.

GEORGE HALL

ONTARIO

The following officers have been elected by the Hamilton Medical Society for the ensuing year: President, Dr. W. J. Deadman, First Vice president, Dr. P. B. Macfarlane, Second Vice president, Dr. D. G. McIlwraith, Treasurer, Dr. C. Gooch, Hon. Secretary, Dr. J. H. Sullivan.

The members of the Hamilton Medical Society are to be congratulated on their Bulletin which made its first appearance in September. This will be issued monthly, and will aim to supply the members of the Society with up to date information in regard to their activities, as well as news items of interest to the medical profession generally.

On September 4th, at a meeting of the Essex County Medical Society held in Windsor, Dr. John Oille of Toronto gave a talk on arteriosclerosis and hypertension.

The Hastings and Prince Edward County Medical Society met at Sterling on September 11th. Dr. R. R. MacGregor of Kingston gave an address on "The malnourished child."

Dr. A. P. Hart of Toronto addressed the North Bay Medical Society on September 12th, his subject being "The physiology and pathology of digestion in infants and its relationship to practical infant feeding."

Dr. W. G. Cosbie of Toronto addressed the Barrie District Medical Society on September 19th, taking as his subject, "Obstetrical injuries and their after results, with special reference to prevention."

At a meeting of the Lincoln County Medical Society held in St. Catharines on September 20th, Dr. R. V. B. Shier gave a talk on "Post operative care."

The Sault Ste. Marie Medical Society met on September 21st, when Dr. H. S. Hutchison of Toronto gave an address on "The treatment of renal disease."

The South Waterloo Medical Society, meeting at Galt on September 21st, was addressed by Dr. D'Arcy Frawley of Toronto, his subject being, "The diagnosis and treatment of acute abdominal pelvic conditions."

On September 22nd, the Porcupine District Medical Society met at Timmins. Dr. H. McCart of Toronto

gave a talk on "Throat diseases with reference to general practice."

The Hamilton Medical Society will hold their annual clinical day on October 25th. A very interesting program is in course of preparation.

N. B. GWYN

Appointments to the Faculty of Medicine, University of Western Ontario, for the next session are: Alan Skinner, M.B. (Tor.), Assistant Professor of Anatomy, Carl G. Smith, B.A., Instructor in Anatomy, R. C. Bradley, B.A., Instructor in Biochemistry, G. W. Stanley, M.D., Instructor in Pharmacology, J. G. Dunlop, M.D., Instructor in Pathology and Bacteriology, R. A. Waud, M.D., M.Sc., Ph.D., Instructor in Electrocardiography, A. J. Read, M.D., Instructor in Orthopedic Surgery, Ivan D. Wilson, M.D., Instructor in Radiology, S. G. Chalk, M.D., M.Sc., and C. S. Tennant, M.D., C.M., Instructors in Psychiatry, A. S. Graham, M.D., Assistant in Anesthesia, Victoria Hospital, and J. L. Daffy, M.D., C.M., D. H. Nichol, M.D., W. C. Sharpe, M.B., and J. R. Howitt, M.B., Instructors in Medicine.

The following promotions have been made: F. W. Hughes, M.D., from Instructor to Assistant Professor of Medicine, and W. J. McLean, M.B., from Instructor to Associate Professor of Physiotherapy.

The officers of the Western Ontario Academy of Medicine, London, for 1928-29 are: Honorary President, Dr. A. J. Grant, President, Dr. E. G. Lewis, First Vice President, Dr. F. W. Luney, Second Vice President, Dr. D. D. Ferguson, Secretary, Dr. E. M. Watson, and Treasurer, Dr. E. L. Williams.

St. Joseph's Hospital, London, has opened a department of physiotherapy and has placed in charge Miss Norah G. Peck, C.S.M.M.G., Eng., a graduate of University College Hospital, London.

J. W. CRANE

Dr. R. B. Jenkins, Edmonton, Alta., Dr. F. W. Jackson, Winnipeg, Dr. F. S. Leeder, Battleford, Sask., and Dr. Eva Mader, Kentville, Nova Scotia, have been appointed to the Connaught Laboratories Fellowships in the School of Hygiene of the University of Toronto.

The fellowships were established last year for the purpose of public health workers in Canada. The appointments are made by the University of Toronto from a list of candidates proposed by the ministers of health in the various provinces.

The Difficulties of Infant Feeding

The failure of the Mother to feed her own offspring may be due to something lacking in her own diet

The remarkably satisfactory results obtained by the addition of Virol to the diet of artificially fed children should be anticipated by the addition of Virol to the diet of the expectant and nursing mother herself

Virol contains Bone Marrow Beef fat Malt extract Lemon Juice and Salts of Lime and Iron Free samples will gladly be supplied to medical men on request

Virol is essentially the food for growth and development. It is peculiarly suited to the maternal needs, supplying concentrated nourishment in a form that does not tax the organs of the digestion or excretion.

By reason of its physiologically correct balance, its vitamin content, and especially because it is so easily assimilable, Virol is essentially the food for growth.

**The Food
for
Growth
and
Develop-
ment.**

VIROL

Forty Million portions of Virol were given last year in 3,000 Hospitals and Infant Clinics in Great Britain.

MANITOBA

Poliomyelitis in Winnipeg

An epidemic of poliomyelitis has appeared in Winnipeg. For three years the city was singularly free, 1925, one case with one death, 1926, no cases, 1927, four cases with one death, but in the middle of July the disease reappeared and up to September 2nd ninety-two cases have been reported with eleven deaths. The worst previous outbreak was in 1920, when forty-seven cases were reported with twelve deaths.

The opening of the schools, which was to have occurred on September 4th, has been postponed until September 17th, and Sunday schools have closed until the disease ceases to have epidemic proportions.

On August 30th an emergency meeting of the Winnipeg Medical Society was held to discuss the situation. More than two hundred doctors were present, and addresses were given by Prof Wm Boyd, Drs Gordon Chown, A. J. Douglas, City Health Officer, Fred Cadham, A. P. MacKinnon, and Dugald McIntyre, Assistant Superintendent of Municipal Hospitals. These six were appointed a committee to prepare articles for the daily press and already one such article has appeared.

The Research Committee is prepared to secure a supply of convalescent serum which may be administered to patients in the pre paralytic stage.

It is hoped that the advent of cooler weather will speedily reduce the number of cases.

The completion of the new Nurses' Home at St Boniface Hospital has rendered possible several alterations in the hospital building, chief of which is the making over of Ste Anne's ward as a maternity ward. In the altered ward, which was opened on September 1st, there are three labour rooms and an up to date nursery.

A considerable addition, which will cost \$45,000, is being built over part of the south wing, thus giving five storeys in place of four. The addition will contain an orthopaedic operating room, a plaster room, two laboratories and a research laboratory, a museum, autopsy room, camera room and dark room, a metabolism room and store rooms. The new addition will allow for expansion of the x-ray department on the fifth floor of the central block.

The contract for the new wing to the Deer Lodge Hospital, Winnipeg, now operated by the Departments of Health and Soldiers' Civil Re-establishment, will be awarded as soon as possible after the tenders are opened on September 4th. The wing will be built on the east end of the present structure and, with a small power house to be added, will cost \$200,000. Later on a wing

of similar dimensions will be added to the other end of the present building, but this will not be done for several years.

Dr Charles Hunter has tendered his resignation as Professor of Medicine in the University of Manitoba. He will, however, continue to take part in the teaching as Associate Professor.

Dr D. A. Stewart, Superintendent of the Manitoba Sanatorium at Ninetto, is in Europe where, with other Canadian tuberculosis experts, he will spend two months visiting sanatoria in the south and west of England, in Switzerland and Italy. He will attend the meeting of the British Tuberculosis Association at London and the World's Anti Tuberculosis Congress at Rome. Special attention is to be paid to methods used in sanatoria for treatment of children. Other western members of the party include, Dr A. B. Alexander, of the King Edward Hospital, Winnipeg, Dr R. G. Ferguson, Medical Superintendent of Hospitals in Saskatchewan, Dr Harvey Boughton, Saskatoon, Dr A. H. Baker, of the Bowness Sanatorium, Alberta, and Dr Lapp, head of the Tranquillo Sanatorium, Kamloops.

The fifth annual Gordon Bell Memorial Lecture, under the auspices of the Winnipeg Medical Society, will be given in October, the speaker being Dr J. G. Fitzgerald, Director of the Connaught Laboratories, Toronto.

Dr Geo Stephens, Superintendent of the Winnipeg General Hospital, returned home on September 16th, after attending the International Hospital Association meeting at Paris.

Dr R. W. Jeffrey, of Monroe, Wash., has located at Carberry, Man.

Dr A. W. S. Hay is now associated in practice with Drs N. J. MacLean, P. H. Theriault and N. H. Blake, of Winnipeg.

Drs C. A. Rice and S. Kobrinsky have been appointed to the honorary attending staff of Graco Hospital, Winnipeg.

A second edition of Dr William Boyd's book on "Surgical Pathology" will appear early in the new year.

Dr Geo Stephens was elected a trustee of the American Hospital Association at the convention of that body at San Francisco on August 10th.

ROSS MITCHELL

SASKATCHEWAN

Dr A. E. Cameron, professor of zoology in the University of Saskatchewan, has been appointed to succeed Dr D. S. Patton in the lecturership in medical entomology, University of Edinburgh, Scotland.

Dr Alexander King, who formerly practised at Gernsey, and for several years past in British Columbia, spent the summer at Lake Maniton, Saskatchewan.

Dr G. A. Parkins has recently come to this province and is now associated in practice with Drs. Leask, Black, Burwell, and Young of Moose Jaw.

Dr W. A. Black has begun practice at Kindersley.

Dr Wm Fotheringham, a graduate of Glasgow, has recently become a Licentiate of the Medical Council of Canada and opened an office at Borden.

Dr H. A. MacLean has begun to practise medicine at Togo.

Dr H. J. Lauden is practising at Warman.

Dr D. Low, for the past two years medical Super-

An ECHO of
THE ANNUAL MEETING OF THE C.M.A.
at CHARLOTTETOWN, JUNE, 1928

"Members of the Profession who visited this firm's exhibit and saw the demonstrations of experiments on the Albino rat must have been impressed with the excellent character of their work and the practical value of the several products which they feature

"This type of pharmaceutical attainment by one of our own Canadian companies is a source of gratification to the Medical Profession and should be encouraged"

MONTREAL - 71 William Street - CANADA

with various phases of medical practice were introduced in the Legislature. Only a few were ever reported out of committee. Those which did pass were largely in the nature of minor amendments and amplifications of existing regulations. The anti vivisection bill on behalf of dogs, and the anti vaccination bill both died in committee.

The Kentucky State Medical Board has again emerged unscathed from a particularly virulent legislative attack on its whole scope and organization. The "Ripper Bill," as it is known in the Blue Grass State, has appeared perennially for a long time. Adherents of the Board claim that this attack is purely political, and in general the Board of Health has had the backing of the medical profession and of the progressive element of the state.

In Washington, the Parker Bill, granting additional research facilities for the Public Health Service, passed but was vetoed.

Bills empowering the Smithsonian Institution to make recommendations for suitable recognition of research and other workers who risk life or health in the public service, and for granting pensions to the survivors of the yellow fever experiments, were reported out of the House committees before Congress adjourned. They will come up next winter—A summary prepared by the American Association for Medical Progress, *Science News Letter*, July 21, 1928.

For some years past research work on Rocky Mountain spotted fever has been conducted by the Montana State Board of Entomology and the United States Public Health Service in a laboratory made out of an abandoned school house. Now, it is to be carried on in a modern three story building, specially designed for the purpose. The vaccine for the prevention of Rocky Mountain fever, produced here by Spencer and Parker, from the bodies of infected ticks has been

tried out on about 4,000 persons with encouraging results.

A further activity of the laboratory is an attempt to exterminate the disease bearing ticks by the introduction of tick parasites. One and a half million of these will be liberated this year.

The eleventh annual convention of the American Dietetic Association will take place at the Hotel Willard, Washington, D C, from October 29th to 31st. Reports of the various Section Chairmen will be given, embodying suggestions for future development. Some well known physicians will also give addresses. Among these may be mentioned "Pellagra," by Joseph Goldberger, United States Public Health Service, "Nutrition and growth," by Lafayette B Mendel, Yale University, "Dietetic treatment in certain of the epilepsies," by H. Rowle Geyelin, Presbyterian Hospital, New York, "Nutrition and the family in social organizations," by Bailey T Burritt, New York.

Visits will be made to the White House, the Library of Congress, Johns Hopkins Hospital, the Walter Reed Hospital, and the Bureau of Home Economics. A number of sight seeing trips are being planned. It is recommended that those planning to attend this convention secure one way tickets, together with a reduced fare certificate. The railroads have granted return transportation at a fare and a third, provided that 250 certificates are presented.

Dr John Farquhar Fulton, who during the past two years has been working in Dr Harvey Cushing's clinic at the Harvard Medical School, has received a three year appointment to a research fellowship at the University of Oxford, where he will carry on research in physiology under Sir Charles Sherrington, and write on the history of physiology and the bibliography of the works of Robert Boyle.

GENERAL

Tour of the Tuberculosis Specialists

Through the beneficence of the Sun Life Assurance Company of Canada a party of physicians, members of the Canadian Tuberculosis Association, sailed for Europe recently. The majority of them were accompanied by their wives. They will visit Liverpool, Birmingham, Cardiff, Winchester, Alton, London, Paris, Nancy, Florence, Rome, Milan, Venice, and then return via Paris, London, Edinburgh, and Glasgow where they will embark on October 27th for the journey home. During the tour the doctors will have an opportunity of studying methods used to fight tuberculosis in Europe, and will visit the principal hospitals and attend clinics. The tour originated with the gift from the Sun Life Assurance Company of Canada, who presented the Association with thirty scholarships of \$500.00 each. Salaried tuberculosis workers were to be the beneficiaries and the President of the Association, Dr Jabez Elliott, was chosen to lead the party. Dr Elliott was one of the earliest medical directors of a sanatorium in Canada, and at present is on the faculty of the Medical School of the University of Toronto. He also is chairman of the medical examiners of the six chest clinics in Toronto and is associated with St Michael's General Hospital, the Hospital for Sick Children, and Preventorium, all in Toronto.

The International Conference of Red Cross Societies

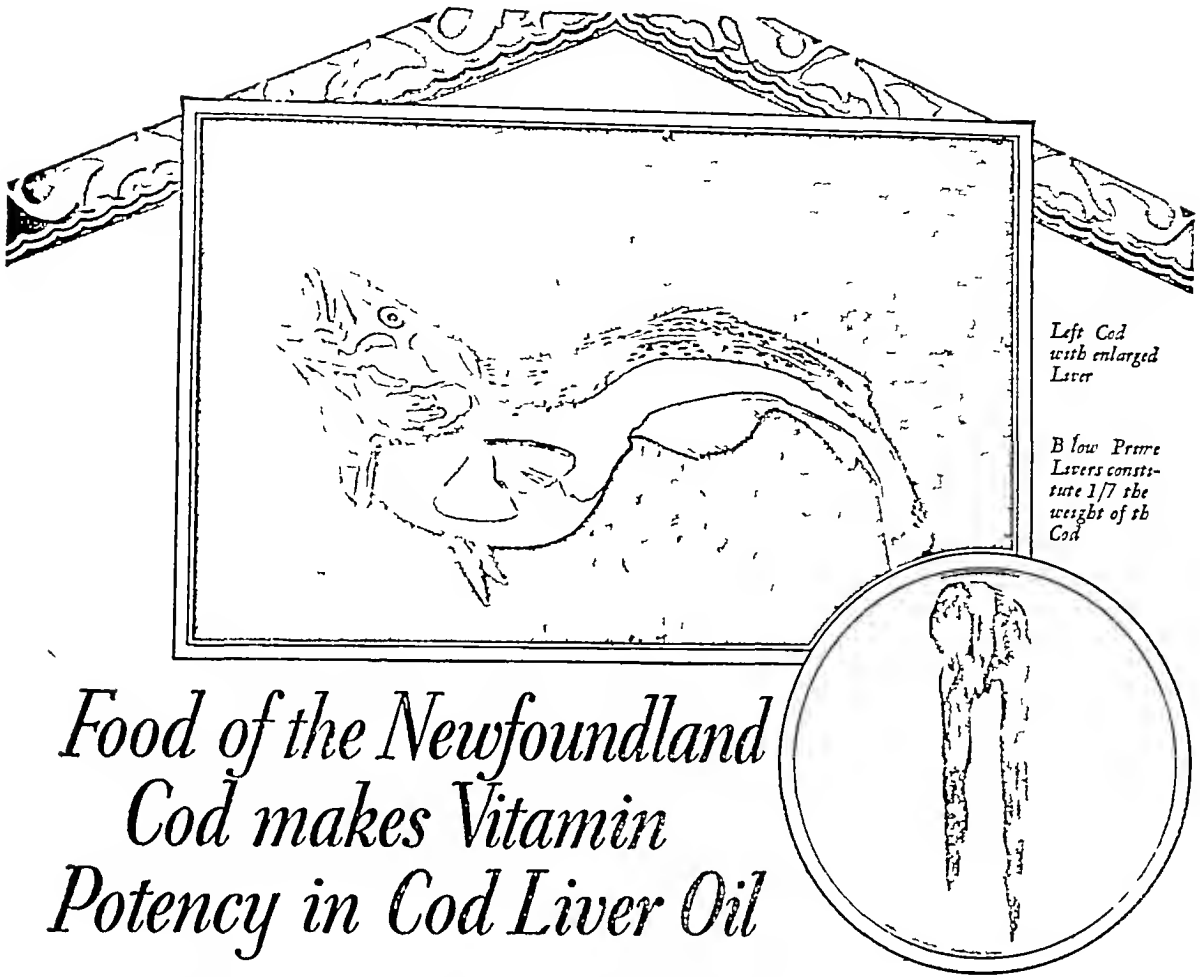

The International Conference of Red Cross Societies, which is held every five years, will convene at the Hague from October 22 to 27, 1928.

Among the topics of interest and importance to be considered are the Red Cross and the protection of the civil population against war gases, attenuation of the evils of a blockade in the case of civil population, the standardization of sanitary equipment, the study of the means to be adopted to lessen war losses, and the relation of the Red Cross to naval warfare.

The new Institute of the History of Medicine at Leyden was inaugurated on June 27th, and is under the scientific direction of Dr J G de Lant, Lecturer on the History of Medicine at the University. The ceremony was presided over by Heer Van Beck Kolonn, representing the Minister of Public Instruction, assisted by the Rector Magnificus, Dr Van Smeek, and the President of the University, Dr de Gyselaar.

Dr de Lant, in his remarks, traced the development of the teaching of Medical History in Holland and the circumstances that led up to the establishment of the Institute. He was followed by M Triet Rozer, the President of the International Society of the History of Medicine, who dwelt on the practical value of the new Institute to students and research scholars, based on his own experience as Professor of the History of Medicine at Louvain.

Dr Ligerist, Professor of the History of Medicine at Leipzig, gave an interesting account of all the institutes for the study of the history of medicine in the world.

Food of the Newfoundland Cod makes Vitamin Potency in Cod Liver Oil

THIS is a typical cod, the liver of which is used in the making of Mead's Standardized Cod Liver Oil—plain and flavored. The belly is enlarged with a huge liver—1/7 the weight of the fish. One seventh the weight of the fish from which the oil is rendered in the proportions of 3 gallons of oil from 5 gallons of livers, when the fish are in the best physiological condition.

In Newfoundland, Cod Liver Oil production under the Mead Johnson policy is a leading industry. Codfish, dried, are by-products. Quite the reverse from other fisheries. The Newfoundland Cod after a season of gormandizing on caplin, squid, herring and sea plant life or algae, are in excellent condition for oil production.

Food in abundance—as high as 52 caplin have been found in the stomach of a single cod—is converted into a biologically certain, potent, vitamin-containing cod liver oil.

Biological Assay

Biological assay in the laboratories of Mead Johnson and Company tests the potency of each batch of Mead's Cod Liver Oil. Rats are used. After a ricket-producing diet, advanced healing must be shown in 5 days according to the Shipley line test.

Book Reviews

Osler's Modern Medicine Vol vi Edited by Thomas McCrae, M.D., and others 964 pages, illustrated Price \$9.00 Messrs Lea & Febiger, Philadelphia, 1928

The third edition of this well known system is now complete. The sixth volume is devoted to diseases of the nervous system, with a concluding chapter on abnormalities of the mind by Edward A. Strecker.

The contributors to this volume are drawn from the leading men in the centres of medical teaching on both sides of the Atlantic. Dr. Lewellys Barker opens with an introduction to the study of disease of the nervous system, with explanations of terms and methods of examination. Diseases of the motor system are considered by W. S. Spiller, and combined system diseases by Dr. Colin K. Russell. Dr. Harvey Cushing contributes a chapter on intracranial tumours. He comments on the perfection of technique in the surgery of brain tumours which has taken place within the last few years, and shows how this requires a special training whose foundations must be laid in the neurological clinic and experimental laboratory for neuropathology. He also contributes a chapter on hydrocephalus.

The chapter on acute encephalitis and brain abscess by the late E. E. Southard has been revised by Dr. J. Ramsay Hunt, and that by the late H. M. Thomas on diseases of the cerebral blood vessels has been revised by Dr. H. M. Thomas, Jr. Diseases of the cerebral nerves are dealt with by Dr. E. W. Taylor, and Dr. Gordon Holmes writes on diseases of the peripheral nerves. The subject of diffuse and focal diseases of the spinal cord is contributed by Sir E. Farquhar Buzzard and Dr. C. P. Symonds, whilst Dr. Smith Eli. Jelliffe writes on hysteria.

This volume is a worthy conclusion to a modern authoritative work on medicine. H. E. MACDONALD

A Text Book of Pathology W. G. MacCallum, Professor of Pathology and Bacteriology, The Johns Hopkins University. XVI and 1177 pages. Price, \$10.00. W. B. Saunders Co., Philadelphia and London, Toronto, McAlinsh and Co., 1928.

This well known and favourite text book has now reached its fourth edition. It is different in its plan from all others. The basic idea is that all pathological disturbances are the result of some form of injury, or of the immediate or remote reactions of the body to injury. In other words disease is discussed from the standpoint of etiology. On the whole, it has been possible to carry out this conception fairly well, but, of course, the system breaks down when the author comes to discuss conditions, such as Hodgkin's disease and cancer, where causes are still nebulous. One advantage of the plan is that there is no division of the subject into general and special pathology. For reasons that seem sufficient to the author certain topics usually dealt with in text books of pathology have been omitted, such as, heredity, the biology of bacteria and other parasites, malformations, and many diseases of the nervous system. Resistance and immunity are touched upon very briefly. The work does not, therefore, pretend to be exhaustive.

In the present edition almost every chapter has been in part or completely rewritten. So far as possible, all recent advances in our knowledge are mentioned, and any changes of opinion on the part of the author have been recorded. The matter has to some extent been rearranged, and certain of the illustrations have been replaced by better ones.

One need not endorse the scheme on which the book is built up, in order to praise it. The scheme admittedly breaks down in places. Only by the widest

charity in the interpretation of the term "injury" is it possible to regard the plan as consistent. This may be illustrated by the case of the disturbances of the glands of internal secretion and the deficiency diseases. Again, it does not make for clearness to consider the blood, lymph, and circulation in three different places. The book begins with a consideration of the disturbances of the fluids of the body, including local disturbances in the circulation of the blood. In chapter XXIII the general disturbances of the circulation are dealt with under the caption of "obstruction." In chapter XLIII the effects of injuries upon the blood and blood-forming organs are considered. Yet, in spite of such criticisms, the work is an excellent one. In every page the author gives evidence of his learning and wide experience. In the case of debatable matters he gives both sides, but usually indicates the current trends of thought. Where we are still feeling our way he brings out the advances in knowledge up-to date. The book may, then, be regarded as a safe one. The histological features of the various lesions are given clearly and fully, and are not overwrought. The illustrations are particularly good, and really do illustrate. At the end of each section a list of the chief articles in the literature is given, which, without pretending to be exhaustive, is sufficient. Having in mind that Dr. MacCallum's work is intended chiefly as a text book for students, it may be truthfully said that it admirably meets its purpose. For the advanced worker, too, it is a distinct advantage to have the considered opinions of so outstanding an authority as Professor MacCallum, one who has himself done much to advance the science of disease.

A. G. NICHOLLS

An Address on Surgical Subjects Sir Berkeley Moynihan, Bart, President of the Royal College of Surgeons of England. 348 pages, illustrated. Price \$6.50. London and Philadelphia W. B. Saunders Co., Canadian agents, McAlinsh & Co., Toronto, 1928.

This collection of essays and addresses shows Sir Berkeley Moynihan at his best, a best which is very good indeed. Few if any other surgeons of the day possess in equal degree his gift of clear fluent writing, and none excel him in graceful oratory. He has been heard in Canada and those who listened to his Murphy oration will not readily forget the brilliance of his tribute to that great surgeon, as he described it himself, "his tribute of laurel for honour, and of rosemary for remembrance." That oration is included in this collection, and in some respects is the best. It is an example too of how he used his subject of the moment as a text for surgery in general, above all for his ideals of surgery, for throughout all these papers he strives to place surgery on the highest possible plane. He tries to show that "even supreme excellence in our art is not enough; that surgery is also the most powerful weapon of research ever placed in the hands of man for his own welfare."

He returns again and again to the inspiring influence of Lister, in the opening Hunterian oration, "Hunter's ideals and Lister's practice", in "Lister as a surgeon," in "Lister,—Benefactor of mankind," and it is with Lister in mind that he develops his ideas of the best training for surgery, "If surgery is to be something more than a wonderful craft, if it is to be the instrument of research which I believe it to have been, and to be destined to be in future, those who practise it must have their minds shaped and strengthened by conflict with unsettled problems, not cramped and sterilized by monotonous exercise within a narrow province of static knowledge. The comradeship of laboratory

Weston's DIGESTIVE

A "whole meal" biscuit
endorsed by doctors and dietists

Weston's DIGESTIVE is a real "health biscuit" made from the original old English recipe of the largest selling health biscuit in the world.

It contains, in delicious palatable form, mild laxative qualities especially suited to convalescents. Weston's DIGESTIVE is the only "fancy biscuit" many dyspeptics can eat.

George Weston Limited, Toronto
Makers of "Biscuits as they are made in England"

workers and clinicians should be intimate and unbroken.

Nor can those who serve the same cause in a different atmosphere give to their patients the best aid of medicine and surgery without the help of the scientist. The training of the surgeon must not only allow, it must urge his mind to stray beyond the hard boundaries of old knowledge, over the edge of firm beliefs, into wide territories as yet unexplored and even undivined. In this way only is their escape from the danger which besets the surgeon in the future, the peril of a facile automatism. In this way may the physiologist be brought back from his vagrancies and encouraged to realize that his science best fulfils its destiny when it is applied to the understanding of the functions, normal and aberrant, of the organs of man."

This is assuredly a book which is pleasant to read, and one which combines historical and reflective writing with teaching on some of the surgical problems of the day.

H. E. MACDERMOT

The Examination of Patients Nellis B Foster, M.D. Second edition, revised 392 pages, illustrated Price \$4.50 London and Philadelphia, W. B. Saunders Co., Canada, McAlmsh & Co., Toronto, 1928

This book is much more comprehensive than the title would suggest. It not only deals with questioning the patient and physical examination, but also contains an excellent discussion of the essential points of differential diagnosis of diseases of the various systems.

The first chapter gives a splendid outline of the method of taking a subjective history. Next follows a chapter on general physical examination, system by system. The author points out the three commoner sources of errors in diagnosis: (1) incomplete data, *i.e.*, having overlooked some point in examination, (2) misinterpretation of data, (3) faulty data. The commonest source of error is incomplete examination. Valuable hints are continually interspersed amongst methods of examination, for example, "Ten per cent of normal individuals have unequal pupils."

The chapter on Febrile Diseases is really a discussion of the differential diagnosis of the cause of a fever, arranged as "Fever with Rashes," "Fever with Purpuras," with jaundice, with arthritis, with diarrhoea, etc.

The next four or five chapters deal with system examinations and diagnosis, all of which are brief and emphasize only essentials.

The chapter on cardiovascular disease is excellent, except possibly the part on hypertension. He states that, clinically, the problem is to decide whether a case be one of essential hypertension or nephritis with hypertension. One is disappointed that the remainder of the chapter deals only with nephritis.

The last chapter is on tests, with detailed directions for taking plates of the gall bladder. One would like to protest against the icterus index replacing the Van den Bergh reaction. Directions are given for extracting duodenal contents, and doing the Lyon's test. The various tuberculin tests are discussed with their clinical application and excellent illustration. He concludes with the Schuck test. Those in connection with scarlet fever are not included.

Though containing less than four hundred pages, the book is an excellent individual exposition on the subject of diagnosis, both for the student and also for all classes of graduates, general practitioners, internists, and even surgeons.

J. O'LE

Clinical Medicine Oscar W. Bethea, M.D., Ph.D., F.C.S., F.A.C.P. 700 pages, illustrated Price \$8.50, London and Philadelphia, W. B. Saunders Co., Canadian Agents, McAlmsh & Co., Toronto, 1928

This is a general practitioner's book. Witness these words from the preface—

"Most of the literature on the practice of medicine

is based on work in fully equipped hospitals or in the homes of the wealthy where every advantage of modern science is available, while as a matter of fact, the great majority of patients must be treated in homes and under conditions offering limited facilities to aid the physician in his efforts. It has been with this larger group constantly in mind that this book has been written."

Approximately 60 per cent of the work is devoted to treatment and throughout emphasis is laid on the individual rather than the case. The book's pages are plentifully besprinkled with prescriptions, but drugs are not unduly lauded. Probably the chief value of the therapy described lies in the detail with which non-medicinal measures are discussed.

The book does not cover the entire field of medicine, but only "about one hundred of the most common diseases." In this list one is surprised to find a friend of other days, *viz.*, chlorosis. Surely this disease is not common still in Louisiana. Many readers will not be satisfied with the sections on hyperthyroidism and hysteria. Nevertheless Professor Bethea's work is readable and instructive. It is well arranged, well printed and well indexed.

G. S. YOUNG

The Clinical Examinations of the Lungs E. M. Brockbank, M.D., F.R.C.P., and Albert Ramsbottom, M.D., F.R.C.P. Second edition 112 pages, illustrated Price 5/- net H. K. Lewis & Co., London, 1928

This small book of one hundred and eight pages is an outline of the authors' teaching on the subject of the examination of the lungs and is published for their students at their request. Being primarily for students, it is somewhat dogmatic at times. This may be beneficial in commencing undergraduate teaching.

A short first chapter deals very briefly with the anatomy and physiology of the chest. The second refers to the essential points in connection with the pain of pleurisy, the causes of dyspnoea, cough, fever, rapid pulse, etc., in pulmonary diseases.

The chapter on inspection is good. The causes of dyspnoea are discussed more fully than in the second chapter. The authors state that a cough frequently arises from disease of any organ supplied by the vagus. Most of us doubt the existence of the stomach cough, and who believes that affections of all of the other abdominal viscera supplied by the vagus can cause a cough? In discussing the different types of cough, that due to passive congestion in cardiac disease might receive more emphasis, so might the offensive odour of the sputum in lung abscess and the hæmoptysis of mitral stenosis.

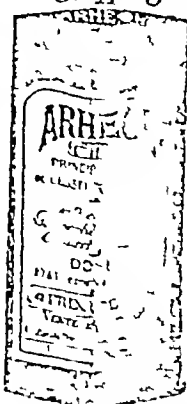

The discussion on palpation and percussion is very good. The chapter on auscultation of breath sounds is orthodox. The varying classifications of adventitious respiratory sounds must be very confusing to students, and possibly to graduates as well. It is difficult to see the justification for classing rhonchi as moist sounds. Certainly some or most rhonchi are due to a narrowing of air passages, due either to swelling or spasm of the bronchial wall. Some, of course, are due to ovoidate or other material within the passage. Then too, most writers on diagnosis classify crepitations as fine (moist) râles, and coarse râles are called "bubbling." The authors restrict the term râle to bubbling or coarse râles, arguing that the crepitations should be restricted to noises produced in alveoli. Who knows whether crepitations are produced in alveoli or terminal bronchioles?

J. O'LE

Text-Book of Infectious Diseases E. W. Goodall, O.B.E., M.D., B.S., Member of the General Nursing Council of England and Wales. Third edition 718 pages, 26 illustrations. Price 30/- net H. K. Lewis & Co., London, W.C.1, 1928

PHYSICIANS SITUATIONS WANTED—Aznos Available Candidates (A) Canadian physician age 34 desires opportunity to learn all phases of Roentgenology. Will start at \$1,800. (B) Canadian OLAR specialist, age 28 single post-graduate work at Manhattan EEN&T Hospital and Vienna two years practicing specialty desires Canadian opening at \$5,000. No 2087 Aznos National Physicians Exchange 30 North Michigan Chicago.

devoted to it therefore require frequent revision, and the volume under review is a new edition to meet such a need. Dr Goodall shows to what proportions the problems of immunology and bacteriology alone have grown, though still as he thinks, without having made much headway. Conflicting statements are made on such a point, for example, as the causation of epidemic poliomyelitis: one school holds that it is due to a filter passing virus, another that a streptococcus is responsible.

In addition to noting the general trend of investigations into the cause and treatment of these diseases Dr Goodall has thought it wise to devote more space to epidemiology, since not only is a knowledge of this subject demanded of those seeking a diploma of public health, but in his opinion the medical student should be taught how important it is to understand the behaviour of diseases in the mass quite as much as in the individual.

The text is clearly and simply written and should from its arrangement commend itself particularly to students. The photographic illustrations of eruptions and rashes are as good as pictures in black and white can be of subjects in colour.

The book may be thoroughly recommended for its clear and comprehensive presentation of modern views on infectious diseases.

H. E. MACDERMOT

Manual of Otolaryngology. Gorham Bacon, A.B., M.D., F.A.C.S., and Truman Laurance Saunders, A.B., M.D., F.A.C.S. 576 pages, 192 illustrations and 2 plates. Price \$4.50. Lea & Febiger, Philadelphia, 1928.

This volume presents an admirable outline of the known facts that daily confront the otologist and the authors have succeeded to an unusual degree in giving a concise treatise on the practical problems of otology.

As stated in the preface, the original purpose was to produce a text book for students as well as a ready reference for the busy general practitioner, and in both cases this has been achieved. Everyone preparing to practise otology should make an effort to acquire a thorough knowledge of the ear and the chapters on anatomy and physiology are well presented both for the student and for those specializing in this line of work.

The subject matter has been revised and brought up to date and a number of proved therapeutic methods introduced. Some of the newer subjects that have been given attention are clearly outlined in the text, such as, the electric audiometer, insulin in the treatment of diabetic patients suffering from mastoiditis, blood transfusion in suppurative ear disease, and the sinus thrombosis manometer test.

On the whole the book is very well balanced and logically arranged. The chapters covering the suppurative diseases of the ear are especially well presented both in the acute and chronic stages and also those on intracranial complications.

Considerable space is given towards the end of the book on deaf-mutism, a subject often neglected in works of this kind. One or two good suggestions are given in the appendix on preparing and staining smears, especially for the streptococcus capsulatus.

If one wished to be critical some of the illustrations might be said to leave something to be desired. For instance the coloured plate showing a normal drum does not picture the pearly grey appearance one is accustomed to see. This might seem superfluous to a practised otologist but to a student it is a point worth while remembering.

G. E. TREMBLE

Studies in the Psychology of Sex. Volume VII. Eonism and other Supplementary Studies. Havelock Ellis. 539 pages. \$5.50. F. A. Davis Company, Philadelphia, 1928.

The publication of this volume completes the well-known series on the psychology of sex by Havelock Ellis, the best known and most comprehensive work on

the subject in the English language. The major problems of sexual life have been discussed in the preceding six volumes and the present one is composed partly of fragments left over from those and partly of studies which, although not wholly sexual, have sexual aspects and relationships.

The first chapter, "Eonism," deals with an interesting anomaly of conduct, namely, the tendency to dress and behave like one of the opposite sex, although not sexually inverted. According to the author's conception, most of such cases have not only no tendency towards homosexuality but feel a profound repugnance to that anomaly. He states that minor degrees of "Eonism" are common, especially in women and at an early age, and one might well have hoped for much discussion of the widespread mannish tendencies in dress and conduct in what seem to be "normal" women at the present time. It is interesting to reflect that a tithe of similar feminine trends in the male would be regarded as very abnormal indeed.

"Undinism" is a study of what may be called vesical psychology. A learned account is given of the influence of water and especially of urination on humanity in primitive and modern times, and also of their sexual aspects. Reference is made to legends and customs collected amongst the Indians of British Columbia, many of which, it is said, have only been published in full in German. Strange, if true! In a short chapter, "The Menstrual Curve of Sexual Impulse," a subject on which very little reliable information seems to be available. On the basis of a very few cases and records, Ellis takes the following points as having been established to a degree: (1) the regular existence in women of a menstrual wave of sexual desire, and (2) the occurrence in that wave of two crests, of which the second roughly corresponds to the period of *Mittelschmerz*. One readily agrees with the statement of the necessity for further careful observations.

Other studies of less general interest are "The Doctrine of Erogenic Zones," "The Mechanism of Sexual Deviation," "The Synthesis of Dreams," "The Conception of Narcissism," and "Kleptomania," that is, stealing associated with sexual excitement. The final study, "The History of Marriage," contains some interesting comments on marriage and married life.

It is worthy of mention as a sign of the times regarding a book on sex that the author has seen fit to restore in the preface an acknowledgment of his wife's help, which he removed from later editions of the first volume, to anticipate possible comment and criticism. With regard to sexual topics to day there would be ready and, in some quarters, almost overdone acceptance of the dictum of Dr. Westermarck, "the concealment of truth is the only indecorum known to science."

This volume, like the preceding ones, is valuable for a wealth of references, literary, historical, and anthropological, and is a worthy ending of a great work. The previous Studies are so well known that it is needless to mention the interest and value the present volume will have for physicians, psychologists, and others whose concern is with human problems.

A Vicious Circle . .

and the proper point for its attack

Is constipation a cause or an effect? This question is occupying much attention among physicians today, for constipation and all the symptoms surrounding it continue to occupy as large a place as ever in human life, and in the doctor's daily practice.

"Constipation is like a headache," argues one authority, "simply a symptom of some underlying physical error or a proper habit of personal hygiene. Worry, inadequate exercise, faulty eating habits, or the habitual use of laxative drugs—these are all influences which produce intestinal impairment."

But if constipation is an effect, it is also a cause. It often causes indigestion, heartburn, bad taste, acid eructations, suppurative diseases of the skin. Careful investigators have concluded that chronic cases of constipation almost invariably produce serious affections of the nervous system—irritability, headache, insomnia, melancholia and what perhaps might be termed *mental stasis*.

CAUSE and effect—action and reaction—a vicious circle. Somewhere the physician must step in and break it up. The authorities cited above point out that thorough investigation of the intestinal tract is essential. The treatment for constipation, they assert, is often all that is required to correct neuros-thenic conditions—"A proper hygiene and therapy of the intes-

tinal tract will often be the deciding factor in differential diagnosis."

For a laxative that does its work easily and naturally many physicians recommend fresh yeast.

Yeast has these advantages. It tends to soften the fecal masses and to increase their bulk and moisture. It diminishes putrefaction and gently stimulates the bowel muscle to perform its function—precisely opposite to the effect of cathartics.

WHILE investigation has shown, in the words of one authority, "that intestinal antiseptics diminish the ability of the intestine to destroy bacteria" the action of fresh yeast is just the contrary. Eaten daily in sufficient quantity, yeast combats the development of hostile types of bacteria in the intestine.

The action of yeast in increasing the number of white cells in the blood accounts for greater resistance and the well known efficiency of yeast in the treatment of acne, boils and other skin diseases.

Physicians usually suggest three cakes daily, one before each meal or between meals. Yeast may be eaten plain or with a sprinkle of salt, spread on crackers, or suspended in milk or water. For constipation it is most effective when dissolved in hot (not scalding) water, one cake before each meal and at bedtime.

A copy of the latest brochure on yeast therapy containing a bibliography of articles and references on the subject will gladly be mailed on your request. The Fleischmann Company, Dept. 473, 208 Simcoe St., Toronto, Ont.

THE GLASS OF HEALTH

Sheltered Sunshine for Convalescents with

Vita Glass

TRADE MARK

Convalescent patients can seldom be taken outdoors with safety owing to the risk of cold winds and sudden changes of temperature. Many medical men are overcoming this difficulty by the use of "Vita" Glass, which transmits the biological and therapeutic wavelengths of the ultra-violet rays that ordinary window glass shuts out entirely. "Vita" Glass introduces into the sickroom a gentle, sheltered heliotherapy which acts as a valuable curative agent and a rapid restorative in convalescence. Now that prices have been considerably reduced, medical men may safely prescribe "Vita" Glass for patients of only moderate means. Those interested in "Vita" Glass for their own homes or for their patients are invited to send for authentic information concerning the notable results obtained in Hospitals, Sanatoria, Schools, Offices, Factories and private houses. May we send you authoritative data on heliotherapy and the interesting story of Vita Glass.

STRICTURES

In the treatment of strictures of whatever sort it is to be remembered that while Fibrolysin softens the fibrous tissue it does not *per se* stretch it. Accordingly, it is necessary also to make use of the appropriate mechanical measures such as stretching, dilating, etc.

Hagenback Burkhardt report a case of *esophageal stricture* in a boy of four which followed the drinking of a solution of caustic potash. One Gm of Fibrolysin was injected every second day under the skin of the back near the spine. The dose was later increased to 15 Gm. After a few injections it was found, upon sounding, that the stricture was relaxing and that there was a corresponding amelioration of the symptoms.

F. B. Adams in a case of *urethral stricture* reports that instead of using the contents of one vial of 23 cc, he used one half of the amount in the morning, the remainder at night, treating the case every other day. On the first and second days there were no perceptible results, on the evening of the sixth day the patient remarked that there appeared to be a slight loosening up, and he could urinate more freely. On the ninth day he was greatly improved, and reported that, aside from a soreness that appeared to be localized at the neck of the bladder, he could urinate as freely as ever. The treatment was continued until six vials of Fibrolysin had been used covering a period of twelve days. He was then given injections through the urethra of the following:

Icthyol
 Acid Boric
 Aquae Destillatae

5 J
 grm
 5 ij

This appeared to remove the soreness from the neck of the bladder—(Merek & Co, Rahway, N.J.)

When a Patient's Feet Retard Recovery, Corrective Shoes are Indicated

A constantly increasing number of physicians observe the necessity of examining patients' feet for causes of trouble in the nervous system. It is often the case that a fault in the feet is the underlying reason for the slowness of recovery from certain ills described as rheumatic, sciatic, etc.

Poor posture, while standing or walking, affects the spine, the abdomen, the nerves, and foot pains caused by uncomfortable shoes discourage regular walking to such an extent that cases of excessive pressure on the cerebral blood vessels are on the increase.

To return feet to normal condition, to aid correct posture and to make walking comfortable and popular, physicians will advise the wearing of Cantilever Shoes, whose main objectives are the preservation of foot health and the correction of foot ills.

Cantilever Shoe

(For Women, Men and Children)

The makers of the Cantilever Shoe are ever open to suggestions and opinions from the medical profession and they have followed the advice of recognized foot experts in designing lasts that embody the essential requirements of a correct shoe, namely—

- 1 Lasts shaped like the average normal foot
- 2 Straighter inner border to provide room for the toes including the great toe
- 3 Snug fit at the ankle and heel for security of step
- 4 Moderate heel heights wedged a trifle on the inside to provide proper proportion of weight distribution and balance
- 5 A flexible shank that swathes the foot arch, holds the foot in its exact place in the shoe, forms a "Cantilever" spring to absorb walking shocks and permits strengthening exercise to the arch muscles.

Any agent will gladly explain in detail the superior features of the Cantilever Shoe. Hundreds of physicians in Canada wear and recommend Cantilevers. For addresses of local agents please write

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION

No. 1, Wimpole Street, London, W. 1.

with which is associated some 50 General and Special Hospitals in London, is prepared to offer the following facilities to qualified practitioners

- I General Courses are arranged covering all branches of Medicine and Surgery. These Courses occupy the student for several hours every day and last for two weeks.
- II For post-graduates requiring less intensive study, comprehensive tickets are issued admitting them to the ordinary hospital practice—ward-rounds, out-patient departments, operations, etc. These tickets permit the post-graduate to make out his own time-table to suit his requirements and all information can be obtained at the office of the Fellowship. The approximate fees are as follows: 1 week, \$10; 2 weeks, \$15; 1 month, \$26; 2 months, \$47; 3 months, \$63; 6 months, \$94; and 1 year \$105.
- III Special Courses are arranged at the Special Hospitals associated with the Fellowship, and these permit of intensive study in one specialty for a period ranging from 1 week to one month.

The Special courses arranged for the ensuing months are —

OCTOBER

Ante-Natal	Oct 26 to Nov 16—Royal Free Hospital. Fridays at 5.00 p.m. Fee £1 1s 0d (limited to 10).
Cardiology	Oct 1 to Oct 12—National Hospital for Diseases of the Heart. All day. Fee £7 7s 0d (limited to 20).
Diseases of Children	Oct 15 to Oct 27—Great Ormond Street Hospital. All day. Fee £3 3s 0d.
Diseases of the Throat, Nose and Ear	Oct 8 to Oct 27—Central London Throat, Nose and Ear Hospital. All day. Fee £5 5s 0d. (Operative Class £7 7s 0d.) (Endoscopy and Pathology Classes).
Gynaecology	Oct 8 to Oct 20—Chelsea Hospital for Women. Morning and/or afternoons. Fee £5 5s 0d.
Tropical Medicine	Oct 9 to Nov 1—London School of Hygiene and Tropical Medicine. Tues and Thursdays afternoons. Fee £2 2s 0d.
Neurology	October/November—The National Hospital, Queen Sq. (6 weeks).
Practitioners' Course	Oct 29 to Nov 10—Hampstead General Hospital. Late afternoons 1½ hrs. Fee £1 1s 0d.

NOVEMBER

Medicine, Surgery and Gynaecology	Nov 12 to Dec 1—Royal Waterloo Hospital. Afternoons and some mornings. Fee £3 3s 0d.
Neurology	Nov 19 to Dec 15—West End Hospital for Nervous Diseases. Daily 5 p.m. Fee £2 2s 0d.
Ophthalmology	Nov 12 to Dec 1—Royal Westminster Ophthalmic Hospital. Afternoons and 1 morning. Fee £4 4s 0d.
Proctology	Nov 12 to Nov 17—St Mark's Hospital. Fee £3 3s 0d.
Urology	Nov 19 to Dec 1—St Peter's Hospital. Afternoons. Fee £5 5s 0d.
Veneral Diseases	Nov 5 to Dec 1—London Lock Hospital. Afternoons and evenings. Fee £3 3s 0d.

DECEMBER

Dermatology	Dec 3 to Dec 15—Blackfriars Skin Hospital. Afternoons. Fee £1 1s 0d.
Diseases of Infants	Dec 3 to Dec 15—The Infants Hospital. Afternoons. Fee £3 3s 0d.
Practitioners Course	Dec 3 to Dec 15—London Temperance Hospital. Late Afternoons 1½ hrs. Fee £1 1s 0d.

Copies of all Special Course syllabuses and of the General Course Programme may be obtained on application. The Hospitals reserve the right to make any alterations necessary in dates and fees. Post graduates are advised, therefore, to make early enquiry.

Special weekly Clinical Demonstrations in Medicine, in Surgery and in Ophthalmology arranged from October to July.

The Clinical Demonstrations and the Lectures are open to all members of the Medical Profession without fee.

Post graduates may become Members of the Fellowship of Medicine and Post Graduate Medical Association, the annual subscription is \$2 50, which includes the subscription to the monthly *Post Graduate Medical Journal*. Subscription to the Journal only \$1 50.

Why the Mercury-Vapor Arc in Quartz for Ultraviolet Therapy?

Consider These Points

Consistent operation contributing to accurate dosage measurement.

Greater output means a given dosage in 1/3 to 1/5 the usual time

Will operate continuously all day without attention

Cleanliness no sparks or fire hazards.

Cost of current consumption negligible

No special wiring—connect to ordinary lamp socket

There are a number of other pertinent facts of interest to every physician or institution contemplating the installation of ultraviolet equipment. Write for full information

TWENTY FIVE years ago the Victor X-Ray Corporation announced to the medical profession an open type carbon arc lamp for therapeutic purposes followed a few years later by another and larger model, "The Sun," the clinical application of which was stimulated by Dr. Finsen of Copenhagen.

A great deal of valuable experience was thus obtained, but even though clinical results reported by Finsen were generally reproduced, the adoption of this source of ultraviolet was limited.

Although the carbon arc type of lamp can be manufactured at a low cost and is consequently more readily sold on a low price basis, the Victor X-Ray Corporation abandoned it with the advent of the *Uviarc*, which produces a mercury vapor arc in a quartz tube having a tungsten anode. The primary object of this development was to produce a quartz vessel without a ground joint and with metallic lead in wires sealed in a vacuum tight manner, so as to permit the use of higher wattage input with a consequently greater ultraviolet output.

The scientific advances in ultraviolet therapy and its widespread adoption in the leading clinics in recent years are coincident with the availability of the mercury-vapor arc in quartz

"To know it is to prescribe it"

¶ Strange how good things often pass unseen. In certain instances this has been found true of LIPOIODINE, "CIBA". ¶ A physician will continue to prescribe the alkaline iodides even after LIPOIODINE, "CIBA" has been called to his attention. Eventually, however, he will give LIPOIODINE, "CIBA" a fair test, and, as a result, will seek no further for an efficient iodine compound. ¶ By virtue of its complete absorption, thorough distribution and slow elimination, LIPOIODINE, "CIBA" has earned for itself the remark—"to know it is to prescribe it." ¶ We will gladly send samples and literature upon request.

The Audotor Tends to Correct Common or Progressive Deafness

A RECENT school survey was quoted by a well-known Medical Journal as indicating that some three million children were expected to show defective hearing when subjected to test.

One can hardly expect a child to either progress rapidly at school or be entirely happy at play if handicapped by poor hearing but unfortunately many are so afflicted.

The Audotor is recommended as a corrective agent in cases of middle ear deafness among children or adults.

It produces rhythmic air wave vibrations of inaudible frequency, periodic exposure to which has a tendency to both increase and sustain the patient's ability to receive and recognize conversational tones.

Systematic treatment in cases where it is indicated is resulting in improvement sufficiently lasting to be considered highly desirable by both physician and patient.

Further particulars in pamphlet form will be forwarded upon request.

McKesson Universal Unit No 100

The McKesson Gas-Oxygen Machine

is not limited to the amount of pressure it can deliver to the patient

The McKesson machine not only regulates the pressure of mixed gases delivered to the patient, but in addition, it maintains that pressure and mixture, and furthermore stops the flow of gases when that pressure is secured, thus preventing any escape or waste of gas due to the accumulation of too much pressure

The McKesson machine is most simply controlled, since one screw, namely the pressure screw, regulates the pressure at which the gases are delivered into the inhaler, and only safe pressures may be administered

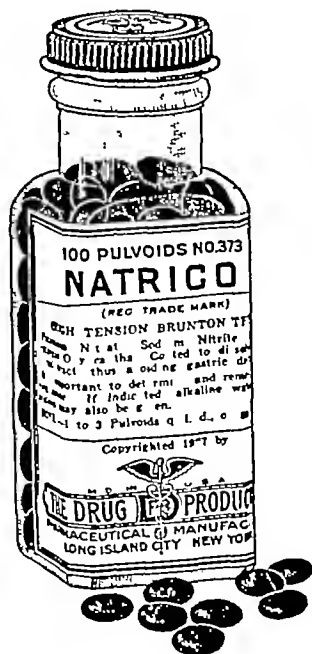

Other unique features are the emergency valve for artificial respiration, the automatic valves, which regulate the intermittent flow of the gases, and the re-breathing attachment which prevents the elimination of too much carbon dioxide from the blood

"Canada Dry"—a popular ginger ale in the sickroom—and rightly, too

TO the physician, "Canada Dry" is a safe ginger ale to prescribe. It is made from the finest quality of Jamaica ginger and other absolutely pure ingredients. These ingredients are blended and balanced with care. They are mixed in exact proportions. Those proportions are never allowed to vary and hourly tests are made to assure that they do not. The purity of "Canada Dry" is a matter of examination, too, under laboratory methods. "Canada Dry" does not contain capsicum. It does not bite the tongue or produce an unpleasant after-effect.

That is why "Canada Dry" recommends itself to physicians all over the country.

But "Canada Dry" is liked by patients, too. It has a mild, mellow, subtle, gingery taste that is delightful. Its uniform carbonation—the result of careful and exact balancing—makes a pleasing change of regimen in the sickroom for the patient. And especially for those patients who have just come out of an ether anæsthetic, it is very welcome. Helping them to overcome nausea as it does, "Canada Dry" goes a long way to starting them on the road to "Now I am going to get well" frame of mind.

Many hospitals regularly stock "Canada Dry" and many physicians regularly prescribe it.

A New EPHEDRINE NASAL SPRAY

for promoting

Sinus Ventilation and Drainage

EPHEDRINE INHALANT, Swan-Myers contains 1% solution of Ephedrine alkaloid in light mineral oil, colored for identification and fragrantly perfumed with oil of rose

It contains no aromatics, such as menthol, thymol, camphor or eucalyptus which frequently irritate and sting. Patients experience no discomfort from the cold air after the use of this spray. Applied as an oil spray, or as drops in the nose, this Inhalant will contract capillaries, reducing swelling of the turbinates and diminish hyperemia. It promotes sinus ventilation and drainage. Its action is prompt and sustained.

WHEN AGE CREEPS ON

When age creeps on apace and physical functions slow down, those so-called minor ailments which one is wont to disregard during the prime of life, assume a new and greater importance.

The processes of repair are slower and less complete in the aged, the power of resistance to infection lessened, and general physical and nerve tone is lowered. Therefore it is advisable in many instances to use synergistic medication in company with the appropriate treatment of many conditions of apparently minor importance, such as colds, obstinate constipation, general fatigue, etc.

No better tonic than Guatonic can be found for sustaining the failing vitality of the old, and aiding in recuperation. It possesses the unique advantage of combining the properties of an efficient general tonic and restorative with the specific action of guaracol and eicosote on respiratory and intestinal systems. William R. Warner and Company, Inc., 113 West 18th Street, New York City, the makers, will be glad to forward samples and literature on request.

SMALL DOSES EFFECTIVE

When we say that one ten-thousandth part of a gram of Adienalmin is sufficient to produce a physiological effect when administered to an adult, we are in the region of the infinitesimal. Adienalmin as used in medicine is never more than one-thousandth of the strength of the original, the best known commercial product is Adienalmin Chloride Solution 1/1000, ampoules are offered containing solutions of 1/2600 and 1/10,000, and for certain uses the strength may be not more than 1 to 100,000.

It is no wonder, then, that Adienalmin has been found capable of reviving the heart action in cases of apparent death, when injected directly into that organ, that it is always thought of in cases of collapse, and that in the paroxysms of asthma it has long been the sufferer's only hope.

Adienalmin, by the way, is a Parke-Davis discovery. Takamine, of the Parke-Davis staff, the first to isolate the pure active principle, made his announcement in April, 1901.

Literature on Adienalmin is offered to physicians by Parke, Davis & Co.

NEO-SILVOL

(Silver Iodide in Colloidal Form)

Non-Irritating · Stainless · Efficacious

NEO-SILVOL is an active germicide containing 20 per cent of silver iodide in a soluble gelatin base.

When tested against the gonococcus, Neo-Silvol has a phenol coefficient of 20, against the streptococcus and the staphylococcus it is as strongly germicidal as pure phenol. It does not stain the skin or clothing and has considerable penetrating power.

Neo-Silvol has been successfully employed in the prophylaxis and treatment of gonorrhea and may be used to advantage in the early treatment of "common colds" and other catarrhal infections of the nasopharynx. In conjunctivitis it acts promptly and may also be utilized in inflammatory affections of other accessible mucous membranes.

Neo-Silvol is supplied in 1-oz. and 4-oz. bottles of the granules, in 6-grain capsules, bottles of 50, as a 5 per cent Ointment in 1-drachm tubes, and as 5 per cent Vaginal Suppositories in boxes of 12.

IMPORTANT to PHYSICIANS ESPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponde's Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician but lacerations leucorrhoea gonorrhoea prolapse, post-operative and post-confinement treatment, and uterine hemorrhage are some of the conditions in which Ponde's Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponde's Tampons.

Ponde's Tampons are packed in six tampons to a box and are made in the following medication

A—Ichthyol Compound, Glycerin and Boro-Glyceride 50% Ichthyol 25% Resublimed Iodine 14% Carbolic Acid (absolute Phenol) 5%, Powdered Hydrastis 1% B—Ichthyol 10% Glycerin and Boro-Glyceride 50% C—Protargol and Ichthyol (Each 2%) Glycerin and Boro-Glyceride 50% D—Opium, Belladonna and Hyoscyamine Glycerin and Boro-Glyceride 50% Powdered Opium 2 grains Extract of Belladonna 1 grain Extract of Hyoscyamus 2 grains E—Glycerole of Tannin 50% F—Ichthyol Compound with Silver Iodide Glycerin and Boro-Glyceride 50% Ichthyol 25% Iodine 14% Phenol 5% Powdered Hydrastis 1% Silver Iodide (made soluble by Potassium Iodide) 1% G—Glycerin and Boro-Glyceride Glycerin and Boro-Glyceride 50% Resublimed Iodine 25% H—Plain Glycerin Gelatin base

Z-12
ZOALITE

THERE ARE HUNDREDS OF CASES that call for the application of clean, dry, penetrating heat for the relief of congestion and pain. The Burdick Zoalite is the safest and most reliable modality for producing a constant degree of heat through the desired period of treatment—not merely superficially, but in the underlying tissues.

The new Z-12 is the latest of the famous Zoalite series with patented features found in no other equipment. It meets every requirement with scientific precision—a convenient, mobile and adaptable unit of equipment.

❖ FIBROSITIS ❖

ALTHOUGH the true nature of muscular rheumatism or fibrositis is not yet determined, authorities generally agree that this affection of the voluntary muscles is almost always due to cold or damp, inducing, in chronic cases, an inflammatory proliferation of the connective tissue

With rest as the first indication, the local application to the affected muscles of a hot

Antiphlogistine

dressing will do much toward the stimulation of a free flow of lymph through the painful part and constitutes a rapid and successful treatment in acute cases

[*"In cases of neurofibrositis kaolin poultice (antiphlogistine) affords in the majority of cases great benefit."*]
Fibrositis—The Prescriber, Nov 1926

Antiphlogistine is no ordinary poultice By virtue of its thermogenetic property it strengthens the tissues by increasing the activity of the circulation, and by diffusing the products of congestion, muscular rigidity and tenderness is diminished bringing with it almost instant relief from pain

HEMABOLOIDS (*plain*) has attained a place of distinction as a general hematinic and reconstructive because it is fundamentally a food iron characterized by ready assimilability

It is a palatable, bland organic iron, which increases red cells, appetite and weight without harsh or constipating effects and is of especial value during convalescence

HEMABOLOIDS ARSENIATED WITH STRYCHNIA is indicated in the more severe or persistent anemias where the iron action must be enhanced by adjuvants **FORMULA**

Each tablespoonful represents

ALCOHOL (By Volume)	17%
IRON (Masked or Nonionic 0.69 grs)	0.92 grs
IRON (Ionic 0.23 grs)	
NUCLEOPROTEINS and PROTEINS	9.6 grs
ARSENIOUS ACID	1/40 gr
STRYCHNIA	1/80 gr

The organic iron of HEMABOLOIDS, being alkali soluble, is capable of ready solution in the intestinal fluids, from which inorganic iron compounds are precipitated. Supplied in 12 oz bottles

SQUIBB'S LIQUID PETROLATUM

PLAIN or with AGAR

SQUIBB'S Liquid Petrolatum (Heavy Californian) is distinctively different from others marketed for intestinal use. It is a chemically pure and heavy naphthene oil owing its superiority primarily to its high natural viscosity.

Squibb's Liquid Petrolatum with Agar was prepared in response to a growing demand of the Medical Profession for a product of this type

which can be prescribed with confidence. It is a superior and palatable preparation having a dry agar-agar content three times greater than similar preparations on the market. The creamy consistency, pleasant taste and proved therapeutic efficacy assure universal favor with patients and physicians. Especially intended for persons having an aversion for plain oils of any kind.

(For complete information write to Professional Service Department.)

Coax the convalescent's appetite with tempting, health-building dishes made from Knox Sparkling GELATINE

BECAUSE of its easy digestibility and protein value, Knox Sparkling Gelatine has been given a high dietetic position, particularly in the regimens of convalescents, the gastro-enterically delicate, and of anorexic patients. As a vehicle for fresh fruits and vegetables, eggs, milk, and in jellied meat preparations, Knox Sparkling Gelatine permits a number of variations in the prescribed diet—dishes which are both appetizing in appearance and satisfying as to bulk.

Knox Sparkling Gelatine is also an important adjuvant in the special protein diets of diabetic patients. In infant feeding, its protective colloidal ability tends to prevent colic, regurgitation, and summer complaint—so often due to imperfect milk digestion. Tests by Downey have shown that Knox Sparkling Gelatine increases the available nourishment of the milk mixture by about 23 per cent.

For 40 years Knox Sparkling Gelatine has been manufactured by a concern devoted to the making of this one standard product. It is pure gelatine, unbleached, unflavored, and unsweetened. From raw material to finished product, every stage in its manu-

CAUTION!

All gelatines are not alike. Many have added acid, flavoring and coloring matter. In the form of ready prepared desserts, they contain as high as 85 per cent carbohydrates.

Knox Sparkling Gelatine is a protein in its purest form, particularly suitable where carbohydrates and acids must be avoided. It contains more than 80 per cent pure protein (4 calories per gram), and has the same neutrality as milk.

Specify Knox when you prescribe gelatine and you will protect the patient from brands unsuitable for his diet purposes.

facture is conducted under sanitary conditions, and is subject to careful laboratory control.

*Valuable booklets prepared by
dietetic authorities*

The booklets listed below demonstrate the value of Knox Sparkling Gelatine in medicine, giving many appetizing recipes for its use in various prescribed diets. These, as well as data on many scientific tests, are available to surgeons, doctors, dieticians and nurses. Check those you wish and mail us the coupon.

KNOX GELATINE LABORATORIES,
453 Knox Avenue, Johnstown N. Y.

Please send me, without obligation or expense, the booklets which I have marked. Also register my name for future reports on clinical gelatine tests as they are issued.

At the root of many troubles

HOW often does diagnosis reveal, as the cause of trouble, faulty functioning of the alimentary canal. Many diseases, more than forty, can be traced to constipation.

In this day of preventive medicine, Kellogg's ALL-BRAN is the physician's ally. It healthfully promotes peristalsis by supplying the necessary bulk or roughage. It is not only effective in relieving constipation, but in preventing it.

ALL-BRAN is 100% bran. Physicians know it can be depended upon to accomplish *complete* results. No part-bran product can do the same.

And patients enjoy Kellogg's ALL-BRAN. Served with milk or cream, with fruit or honey added, or in cooking, its appetizing nut-like flavor makes it a delightful "prescription."

Made by Kellogg in London, Ontario.
Sold by all grocers. Served everywhere.

When Non-Specific Protein Therapy is Indicated - - Employ

AOLAN

A lactalbumin suspension, free of bacteria and bacterial toxins and therefore producing no by-effects. AOLAN is indicated in all forms of infection.

Literature and Samples from

MALLINCKRODT CHEMICAL WORKS, Ltd.

378 St. Paul Street West, — MONTREAL

An Endocrine Tonic

An acute infection, an infectious disease, a surgical operation, a chronic toxemia—all deplete the endocrine regulators. First stimulation, then overstimulation and depletion. As a result, the functions maintained by these hormones are below par, the muscle tone is poor, cellular chemistry is reduced, and the toxemia is aggravated—in short, a vicious circle is established. Granting that the cause is controlled, there are three important things to do: Increase elimination, neutralize toxemia (acidosis), and support the endocrines.

Adreno-Spermin Co. (Harrower)

effectively accomplishes these three things. This endocrine tonic is indicated in the fatigue syndrome, post-influenzal asthenia, subnormal temperature, low blood-pressure, and hypoadrenia. It is as rational a form of therapy as one can expect to find—and highly efficient in indicated cases.

Dose: One sanitablet q i d for several months.

TORONTO, 2

For the Delicate Child

THE delicate, backward, nervous or unstable child is ever a problem in the children's clinic. Very frequently faulty metabolism lies at the seat of the trouble, involving an inherent incapacity to make adequate use of the essential and vitalizing elements of ordinary nourishment.

Liberality of the nitrogenous or building elements of the diet to the limit of digestive capacity is recommended by authority. Two teaspoonfuls of "Ovaltine" dissolved in half a pint of milk produces a tonic and nutritive beverage well adapted to this requirement. It gives a protein to non-protein ratio of approximately 1 to 3.5 which is a liberal apportionment of the nitrogenous element. The proteins of "Ovaltine" are those derived from "Winter" Malted Barley, Eggs and Milk, valued sources of nutritive material for the delicate child.

OVALTIN

TONIC FOOD BEVERAGE

Such a diet taxes to the minimum the digestive function because "Ovaltine" modifies the milk curd to a light, easily digested coagulum. Moreover, clinical evidence plainly shows that "Ovaltine" is well borne in spite of food intolerance, anorexia and those numerous perversities of alimentation which undermine the constitution and frequently result in permanent injury.

A liberal supply sent free for clinical trial on request

"The Line Test" In Infant Feeding

*I*F medicine had been born a complete science, if the law of variation could be suspended, it is conceivable that the sum and total of human knowledge could be encompassed in a single volume, the science of medicine could consider its conquests complete and its responsibilities for further research ended

But this is not the case. Exceptions constantly appear, the old order is found to possess its limitations, necessity, the mother of invention, provides another and still greater urge. So finally is always in the offing—the last word is never spoken

It was the recognition of the law of variation that prompted the assertion that each infant is a law unto itself and feeding must be adjusted to its individual needs. Even then, exceptions arose, they still arise and from these necessities, progress in the art of infant feeding and science in the preparation of infant diet materials emerges

Resources are valuable only as they are assembled to serve greater and ever varying ends. To exercise his own resources to their fullest extent, to enjoy the selective principle with the utmost freedom, the physician demands a latitude in the choice of dietary materials at his disposal, just as infants demand a wide variation to suit their needs

This then, is the test, not a single product, but a *line* of infant diet materials that increases the range and scope of the physician's skill just as it increases our alertness and zest to serve his needs

Dextri Maltose—A highly assimilable carbohydrate for cow's milk modifications

Recolac—A reconstructed milk for traveling or where the milk supply is faulty

Casec—The principal protein of cow's milk, for the correction of fermentative diarrhoea

Cod Liver Oil—Standardized as to potency, produced exclusively from Newfoundland Cod

Protein Milk—Now available in a form that is boilable for a 10-minute period

Malt Soup Stock—For use in cases of an idiosyncrasy against carbohydrate

"A Perfect Combination of Malt Extract with Cod-Liver Oil"—*B M J*

'Bynol' contains 30% by volume of the highest grade Norwegian Cod-Liver Oil very finely emulsified with the "Allenburys' Malt Extract and aromatics, thus producing a rich, easily digestible and palatable product. The main ingredients, particularly the Cod-Liver Oil, are rich in vitamins which are conserved in their full potency by the special processes used in the manufacture of the product. "Bynol" is of special value to those who require additional fat and vitamins beyond what is supplied by an ordinary dietary—to backward and weakly children, nursing mothers, and those suffering from malnutrition or having a predisposition to phthisis and respiratory diseases in general. The usual dosage is from one teaspoonful to one tablespoonful three times a day after meals.

*Clinical trial sample will be sent post free
to members of the Medical Profession.*

The ALPINE SUN LAMP

Two important thoughts . . *on ultra violet light-therapy*

WHICH LAMP TO CONSIDER . . . and WHAT TO READ

THE first consideration in the purchase of an ultra violet lamp is the production solely of ultra violet rays in quality and quantity—efficient enough to carry on the proper therapeutic procedure. The HANOVIA Quartz Lamps, the ALPINE SUN and KROMAYER do just these things. They were the originators of the use of ultra violet therapy in this country, and on them the present standard technique has in the most part been based and the clinical results founded.

The question of literature on the subject is an important one, and the material is voluminous. We suggest the reading of the current work on the use of ultra violet light for diagnosis. With the use of the quartz lamp and the proper filters, the fluorescent properties of the ultra violet light on the skin react differently according to the nature of the disease. Though known about for sometime, only recently have active reports of this work been published. Mail in the attached coupon for this data.

GRAY'S GLYCERINE TONIC COMP.

Formula Dr. John P. Gray

CONSTITUENTS

Glycerine
Sherry Wine
Gentian
Taraxacum
Phosphoric Acid
Carminatives

DOSES —Adults Two teaspoonfuls to a table-spoonful in a little water before meals, t.i.d (or after meals when preferred)

Coughs, Colds, Bronchitis, Teaspoonful every two hours, clear

Children —One-half to one teaspoonful

INDICATIONS

Malnutrition
Anaemia
Neurasthenia
Melancholia
Atonic Indigestion
Catarrhal Conditions
General Malaise

Gray's Glycerine Tonic Compound has proven the ideal Tonic at all seasons of the year for the sufferer from Chronic Organic Disease—Malnutrition, or debilitated conditions generally.

An Address ON REFLECTIONS OF AN ANÆSTHETIST*

By W B HOWELL, M.D.,
*Chief Anæsthetist, Royal Victoria Hospital,
Montreal*

MAY I be allowed first of all to express the very great pleasure which we members of the Canadian Society of Anæsthetists feel in having this opportunity to hold a joint meeting with the members of the Eastern Society. Nothing but good for ourselves and our specialty can come of such gatherings, and I earnestly hope that they will become a regular institution. No more appropriate place than this interesting old city could have been chosen for a meeting like this—firstly, because of its associations with the history of anæsthesia, and secondly because it was here that your forefathers and ours laid the best of all foundations of a lasting friendship by the time-honoured process of having a good stand-up fight.

I have chosen for the subject of my address some of the thoughts which have of late become more or less regular visitors to what I call my mind. There are other thoughts, illicit visitors, that come to me in moments of exasperation and depression. About these, from motives of prudence, I shall say nothing. If the day ever comes when I shall be able to retire, I should like to publish them in the form of a valedictory to the medical profession. That will be my swan song.

Now in the first place, what do I really think about our specialty? If I had my life to live

over again would I be an anæsthetist? My answer is unhesitatingly "Yes." I know that there are certain disadvantages which are not found in other specialties, but in my opinion they are far outweighed by one great advantage. Because nearly all surgical operations are performed in the morning or early afternoon we have a certain amount of that inestimable boon, leisure. We can keep ourselves familiar with everything that is worth reading in our specialty, and yet have time at our disposal for something else than the business of earning our daily bread. It requires all my little stock of moral courage, in such a strenuous age, to speak of leisure in this way. I may confess here that I am in no way impressed by the strenuous man who works ten or twelve hours a day. I have come to believe that when a working day lasts longer than eight hours the quality of the work for the whole day suffers. So I feel rather sorry for my strenuous friend. He may work early and late because he has erected the doctrine of "hustle" into a fetish or he may be a successful doctor overdriven by his patients. Whatever the reason, he puts an excessive amount of time and energy into doing work which is not his best. Let him be careful not to take the cab-horse for his model lest, he also find himself with a drooping head and a range of vision limited to the road at his feet. In the course of time my strenuous friend will, no doubt reap his reward and achieve the objects of his am-

* The Presidential Address before the Joint Session of the Eastern Society of Anæsthetists and the Canadian Society of Anæsthetists, Boston, October 8-12, 1928.

largely a process of discarding wrong old practices in favour of wrong new ones

I have recently been reading the highly entertaining preface to Bernard Shaw's "Doctor's Dilemma," and learning what villains we doctors are. "The medical profession," he says, "has not a high character, it has an infamous character." And again, "It is simply unscientific to allege or believe that doctors do not, under existing circumstances, perform unnecessary operations." Now, it is of course true that there are rascals in our profession, as there are in all other walks of life, and that there is a certain number of operations done from a mixture of unworthy motives, chief among which are the need of money and the wish for practice or advertisement. But in large hospitals there is a powerful deterrent about which Bernard Shaw was ignorant and that is the watchful eyes which are focussed on the surgeon when he is in the operating room. If he makes a mistake it is known in a few minutes all over the hospital. If there is a suspicion that he has operated without good reason every one knows, and no one gives him the benefit of the doubt. The light which shines upon his reputation is fiercely bright. The best antiseptic of the operating room is the criticism of colleagues, the wholesome influence of which is reinforced by the fear of public opinion as crystallized in the minds of remote beings known as "governors."

Bernard Shaw in the preface from which I have quoted asks the question "Are doctors scientific?" In unequivocal language he answers his own question in the negative. "As a matter of fact," he says, "the rank and file of doctors are no more scientific than their tailors." Whether we think Shaw right or wrong depends on what meaning we attach to the word "science." If we mean by "men of science" men who are intellectually honest, who want to find out the truth and to publish it stripped of all the obscurity which tradition, imagination, prejudice and self-interest throw over it, then I think we must be careful how we pride ourselves on being scientific. It is because we do not vitally care whether we have truth itself served up to us, or error dressed up to look more or less like truth, that medical literature in journals and books has attained its present monstrous proportions. In spite

of our training in science ours is the most credulous of professions.

A year or two ago I read in a leading French medical journal an address given by one of the most famous surgeons in Europe upon the subject of general anaesthesia by the spinal injection of stovaine. For twenty years he had used this method of anaesthesia to the exclusion of all others, in every kind of operation in general surgery "sans accident, sans mortalité." Now, having had a fairly wide experience of general and spinal anaesthesia, I confess I was a little incredulous. Could anyone, I asked myself, carry on a large surgical practice for twenty years, and never have an "accident" or a death on the table? If he had had such a death or an accident could he be quite sure, in view of the fact that he was using the spinal injection of stovaine for general anaesthesia, that the anaesthetic played no part in it? It was a good deal to ask one to believe. But what sort of anaesthesia did he get? On this point I received enlightenment from a friend who had seen the great man operate upon a patient with cancer of the breast. "The patient," he said, "suffered a great deal of pain during the operation."

Here is another example of the truth which is not the whole truth. A distinguished surgeon and teacher of surgery some years ago operated within the space of a month or two upon four patients, who by reason of intemperate habits, obesity, and disease of the lungs were considered unsuitable for general anaesthesia. Three of them were given a spinal anaesthetic and made excellent recoveries. An attempt was made to give the fourth a spinal injection but resulted in failure owing to the impossibility of introducing the needle into the subdural space. He was then given ether and made as good a recovery as any of the other three. Now the surgeon reported the first three cases and said nothing about the fourth although his paper was written to show the place of spinal anaesthesia in certain operations where general anaesthesia is contraindicated.

Had Bernard Shaw thought of turning to medical writings for evidence to support his statement that we are no more scientific than our tailors I am afraid he would not have had to search far. He would have found it in the slipshod use of language which has unfortun-

ately become so common, and which can arise from no other cause than slovenly ways of thinking. As an example of what I mean I shall quote the following sentence which is taken from an article written by a member of the surgical staff of one of the great clinics of North America. "The consideration of operation in the presence of the degenerative cardiac diseases must be individualized and based entirely on the prognosis of the particular type of disease as ascertained by clinical and electrocardiographic studies, considered in conjunction with the urgency of the operation and the effect on the cardio-vascular system of removal of the surgical burden." Now, what I ask, is all this about? The use of the word "individualized" I find especially confusing. I looked up the word in the dictionary, and found that it means, "to give individual character to, to specify," and I wondered how one can individualize a consideration.

Another example comes, I regret to say, from a paper written by an anæsthetist. "Respiration during induction," he writes, "may terminate in apnoea even though they (the patients) are still too light to initiate surgical procedure." Passing over the colloquial sense in which the word "light" is used, we have here a statement from which we are justified in inferring that when the patients are more deeply under the influence of ether they will begin to operate upon themselves.

I have never heard any plausible explanation of the confusion of tongues which put a stop to the building of the Tower of Babel. My own theory is that everyone employed upon that work adopted the position of Humpty Dumpty in "Through the Looking-Glass." "When I use a word," said that bold philologist, "it means just what I choose it to mean, neither more nor less."

In this same spirit we have dealt with the

word "pathology." Originally it meant, if we may judge by its derivation, "a discourse on disease." It is now also a synonym for "disease." A patient with bronchitis has "lung pathology." To realize fully how confusing is this sort of innovation we have only to subject other words ending in "ology" to the same treatment. Theology becomes a synonym for God, and the Revised Prayer Book of the future will contain a creed commencing with "I believe in theology." An atheist will be one who "does not believe in theology." "Phrenology" will come to mean "mind," and a madman will be one who has "gone out of his phrenology." If by the time he recovers, the word "physiology" has acquired the meaning of "health," he will be said to have recovered his "phrenological physiology." Shall we be justified in feeling sorry for him if he relapses?

It is no excuse for writing carelessly to plead that one has not time to do better. Readers do not hear the excuse. What is badly expressed they find difficult to understand, and will not bother to read. "If your language is jargon," says a great modern teacher, "your intellect, if not your whole character, will almost certainly correspond. Where your mind should go straight, it will dodge, the difficulties it should approach with a fair front, and grip with a firm hand, it will be seeking to evade or circumvent. For the Style is the Man, and where a man's treasure is, there his heart, and his brain, and his writing, will be also."

There are several other subjects about which I should like to speak, but I refrain out of consideration for the feelings of the gentlemen who have arranged the program of this meeting. I know that to them long-windedness is the unpardonable sin. I hope I have not offended too deeply.

/

A Medical Family—In August, 1828, Matthew Baillie Gairdner became a licentiate of the Royal College of Surgeons of Edinburgh, at the early age of 19, he graduated M.D. at the University of Edinburgh two years later, and became F.R.C.S.Ed. in 1858, he died in 1888. His eldest son, James, graduated M.B., C.M.Ed. in 1867, proceeded M.D. in 1873, and has acted as medical officer of Crieff Parish in Perthshire for more than sixty years. The professional practice of father and son has thus

covered more than a century. It would be interesting to know if this record can be approached by any other medical family. Dr. James Gairdner's younger brother, Matthew William Gairdner, graduated M.B.Ed. and obtained the diploma of L.R.C.S.Ed. in 1871, he resides at Cheltenham, and his son, Alan Campbell Gairdner, is a medical graduate of Oxford and obtained the L.R.C.S. Eng. this summer—*Brit. M. J.* 1928, ii, 583.

An Address ON THE FIELD OF NEUROSURGERY*

By WILDER PENFIELD, M.D., B.Sc. (Oxon),

Clinical Professor of Neurosurgery, McGill University, Montreal

THE differences between the American and Canadian medical profession have little to do with science and much with tradition and background. For me, to leave the one and enter the other is made easier by years of medical study in Great Britain, and because of the fact that I can claim as my teacher and friend, a great Canadian, Sir William Osler.

Such a change is apt to cause one to look questioningly at the divisions between the ever more specialized branches of our profession. New knowledge, and a multitude of new technical procedures, have made it impossible for any man to master all of the intricacies of medical science, even though he were endowed with the many-sided capacity of Leonardo Da Vinci, or John Hunter. But a fair and efficient adjustment even between medicine and surgery, has long offered difficulty. It is my desire to speak briefly of this relationship, at least in so far as it concerns the treatment of diseases of the nervous system.

Neurosurgery is perhaps the youngest of medical specialties. Operations upon the central nervous system were naturally doomed to failure until Lister had given us the secret of the control of sepsis, and Ferriar had provided the clue to localization of function in the brain, for sepsis within the meninges spells death and blind exploration may mean paralysis.

Neurologists who early saw the goal to be attained called upon surgeons who did not understand the goal and who were ignorant of the physiology of the nervous system. The results were terrible and the profession gradually concluded that the unfortunate patients might as well be allowed to die in their own way. This attitude, which can be dispelled only by demonstrated results, lingers still in many localities.

Effective neurosurgery may be said to begin

with Sir Victor Horsley. He started his professional career as a surgeon but before he began his work upon the human nervous system he had made of himself a neurophysiologist, and years of experimental surgery had enabled him to develop a technique for such operations. With his use of bone wax, heat, and bits of muscle for hæmostasis, and his daring approach to all regions of the brain and spinal cord Horsley was a pioneer, and must always be considered the great figure in neurosurgery. MacEwen, of Glasgow, at about the same time demonstrated the proper treatment of abscesses of the brain, and left behind him an almost unbelievably low mortality record in the treatment of this affliction.

Following Horsley, Cushing has refined the methods of neurosurgery and has demonstrated once and for all that these operations may be done with a low mortality by a specialized team. In his clinic it was first proved that simple craniotomy could be done with little more risk than that involved in ecchotomy. Dr. Cushing's statistics have turned a new page in the surgery of tumours of the brain and hypophysis, and there are a score of his pupils scattered through America and Europe, restricting their work to this type of surgery and reproducing his results according to their several ability.

In Philadelphia the fortunately combined efforts of a neurologist, Dr. Spiller, and a neurosurgeon, Dr. Frazier, have provided us with a permanent cure for trigeminal neuralgia by differential section of the posterior root, a procedure which, in experienced hands, has practically no operative mortality. They have also given us another means of liberating patients from unbearable pain, *i.e.*, chordotomy, or section of the tracts which conduct pain in the spinal cord.

Dandy has provided us with a new method of cerebral localization, *i.e.*, roentgenography of the cranial cavity after direct ventricular re-

* Delivered before the Montreal Medico Chirurgical Society, November 2, 1928

placement of fluid by air or after similar spinal replacement. Thanks to this method, which should, however, be used only in doubtful cases, the diagnosis of unlocalized brain tumour is now practically never justified.

Such injections of air into the spinal canal may also be used as a specific cure for traumatic meningeal headache. There are many more advances in the field of the central nervous system and also the peripheral and sympathetic nervous system which may not be mentioned here.

Thanks to peculiar conditions in American professional and university life it has been possible for an ever increasing group of men to confine their activity to neurosurgery. The result has been a rapid expansion of this specialty. In one western city of the United States there are at present seven neurosurgeons, only one of whom is dependent upon a university budget for his income.

On the continent of Europe on the other hand, there has been no such specialization. Every general surgeon has held himself ready to do any operation upon the nervous system which may, by chance, be entrusted to him. The result has been little or no advance in surgical therapy. At the same time neurology on the continent seems to have failed to fulfill the brilliant promise of such clinicians as Marie, Déjeune and Oppenheim. The university chairs created for combined neurology and psychiatry have come gradually to be occupied by men whose interest is largely psychiatry.

In two neurological clinics, however, which are perhaps the most distinguished on the continent to-day, a new stand has been taken. Foerster, Professor of Neurology in Breslau, now carries out all of his own operations, and has become the leading and almost the only neurosurgeon in Germany. Brouwer, of Amsterdam, has induced his native city to send one of his assistants abroad for training in neurosurgery that he may return and operate within the university neurological clinic.

The future of neurology and the future of neurosurgery alike demand that these two specialties be combined in one. Herein lies salvation and guidance for both. A surgeon who operates upon the nervous system without

studying both the subject of neurology in general, and the neurological problems of his patient in particular, works under too great a handicap, regardless of his manual dexterity. The prerequisite training is similar for neurology and neurosurgery, and neither can do without the other. It is true that not every neurologist is in a position to operate and likewise the surgeon who may spend two to five hours upon his feet in each major operation finds it quite impossible to treat non-operative neurological cases. There must be a professional subdivision of the material treated.

The neuropathological, neurophysiological, and clinical interests of medicine and surgery must be identical. The common meeting ground is above all the neuropathological laboratory. Comparative segregation of neurology and neurosurgery with their own methods of research and study is the *sine qua non* of future advance.

On the other hand, it is true that too great specialization is dangerous, and neurology and neurosurgery need the steadying influence of an association with general medicine and surgery, which should be as intimate as hospital life will permit. Aside from the clinic, the closest contact which this double specialty makes with surgery is through the operating room, with medicine through the research laboratory.

The field of neurosurgery, both now and in the future, should not be confined to tumours of the nervous system and the douloureux as is the case in some clinics. On the contrary, it should include the prevention and the cure of traumatic epilepsy, control of cardiovascular pain and of intractable pain of all types, traumatic headaches and some types of migraine, birth hæmorrhage and the ensuing epilepsy, peripheral nerve injuries and even some cases of pyogenic meningitis and hydrocephalus. These and other involvements of the nervous system open up a wide and much neglected field of activity.

The future promises much. New methods will surely solve many of the unsolved problems. In no other department of medicine is the need for new work more challenging, and in my opinion nowhere else is the discovery of scientific gold so certain.

ULCERATIVE COLITIS*

By P H T THORLAKSON, M D, C M, M R C S

*Lecturer in Clinical Surgery, Medical Faculty, University of Manitoba,
Surgeon, Out-Patient Department, Winnipeg General Hospital,**Winnipeg*

THE subject of ulcerative colitis has received a great deal of attention in the medical literature of all countries during the past decade. In reviewing the English, German, French and American literature on this disease, one is struck by the similarity of the articles. It seems obvious that these writers from various countries are all dealing with the same condition, and not, as has been suggested, with different diseases brought under the same name—ulcerative colitis. The term is undoubtedly unsatisfactory from the etiological standpoint, but the condition has been so adequately described, both in regard to its pathology and clinical manifestations, that no confusion should exist regarding the condition it is intended to designate.

One can summarize the present state of our knowledge of the disease in this way. Ulcerative colitis is a disease which is essentially chronic, but is subject to acute or sub-acute exacerbations. The exact etiological factor is unknown, though it is almost universally agreed that it is an infectious disease of which the specific micro-organism has not been definitely isolated. The pathological lesion is typical and constant, being an erosion involving only the superficial layers of the mucosa in the earlier stages, but associated with oedema, congestion, and leucocytic infiltration of the entire bowel wall in the more advanced cases. While the whole length of the large bowel is frequently involved, the brunt of the disease is carried by the rectum and sigmoid. The clinical manifestations are diarrhoea with from six to thirty stools a day, which contain blood, pus, and mucus. A varying degree of secondary anaemia is always present. Loss of weight, in spite of a fairly good appetite, a slight temperature, leucocytosis, and cramp-like abdominal pain relieved by evacuations, are symptoms of minor diagnostic value. The sig-

moidoscope is indispensable in arriving at a correct diagnosis. The X-ray assists in the diagnosis by excluding other causes of diarrhoea, it also helps to determine the extent of the disease, it shows hypermotility of the colon with absence of normal haustrations, the typical pipe-stem or ribbon-like colon. (See Fig 1)

Finally, the treatment is not standardized, owing to the fact that we do not know the exact micro-organism with which we are contending, but in spite of this serious handicap the results from active and thorough treatment carried over a period of months in every case are on the whole quite satisfactory.

BACTERIOLOGY

In discussing the possible etiology of this disease, mention must first be made of Baigen's work which constitutes a noteworthy contribution to the study of this malady. Future advances in our knowledge of the disease will perhaps depend entirely upon bacteriological research. Baigen has described a non-mannite fermenting diplococcus which he considers to be the causative agent. He has been able to isolate this organism in about 75 per cent of his cases, and has noticed an improvement from vaccine therapy. At first this seemed most encouraging, but our experience during the past year has not been such as to make us feel that this was the solution of the problem. In one of my cases, I was able to obtain a fairly pure culture of this diplococcus from a superficial smear taken from the rectal ulcers and an organism morphologically similar from an abscessed tooth. This patient showed a marked improvement after extraction of the affected tooth and a repeated course of vaccine, but it is difficult to be sure which was chiefly responsible for this improvement. She has had very thorough treatment with the diplococcus vaccine, but has had relapses and is far from well. From clinical ob-

An Address

ON

REFLECTIONS OF AN ANÆSTHETIST*

By W B HOWELL, M D,

*Chief Anæsthetist, Royal Victoria Hospital,
Montreal*

MAY I be allowed first of all to express the very great pleasure which we members of the Canadian Society of Anæsthetists feel in having this opportunity to hold a joint meeting with the members of the Eastern Society. Nothing but good for ourselves and our specialty can come of such gatherings, and I earnestly hope that they will become a regular institution. No more appropriate place than this interesting old city could have been chosen for a meeting like this—firstly, because of its associations with the history of anæsthesia, and secondly because it was here that your forefathers and ours laid the best of all foundations of a lasting friendship by the time-honoured process of having a good stand-up fight.

I have chosen for the subject of my address some of the thoughts which have of late become more or less regular visitors to what I call my mind. There are other thoughts, illicit visitors, that come to me in moments of exasperation and depression. About these, from motives of prudence, I shall say nothing. If the day ever comes when I shall be able to retire, I should like to publish them in the form of a valedictory to the medical profession. That will be my swan song.

Now, in the first place, what do I really think about our specialty? If I had my life to live

over again would I be an anæsthetist? My answer is unhesitatingly "Yes." I know that there are certain disadvantages which are not found in other specialties, but in my opinion they are far outweighed by one great advantage. Because nearly all surgical operations are performed in the morning or early afternoon we have a certain amount of that inestimable boon, leisure. We can keep ourselves familiar with everything that is worth reading in our specialty, and yet have time at our disposal for something else than the business of earning our daily bread. It requires all my little stock of moral courage, in such a strenuous age, to speak of leisure in this way. I may confess here that I am in no way impressed by the strenuous man who works ten or twelve hours a day. I have come to believe that when a working day lasts longer than eight hours, the quality of the work for the whole day suffers. So I feel rather sorry for my strenuous friend. He may work early and late because he has erected the doctrine of "hustle" into a fetish, or he may be a successful doctor overdriven by his patients. Whatever the reason, he puts an excessive amount of time and energy into doing work which is not his best. Let him be careful not to take the cab-horse for his model lest, he also find himself with a drooping head and a range of vision limited to the road at his feet. In the course of time my strenuous friend will, no doubt, reap his reward and achieve the objects of his am-

* The Presidential Address before the Joint Session of the Eastern Society of Anæsthetists and the Canadian Society of Anæsthetists, Boston, October 8 12, 1928

bitions, but it will be at the risk of finding that the fight has left him too battered in soul and body to enjoy them. To such as he the prophet spoke, and spoke in vain, when he said, "The wisdom of the scribe cometh by opportunity of leisure." I do not mean to imply that one necessarily becomes wise because one has leisure. Modern civilization provides only too many ways of passing time without benefit to our souls, our minds, or our bodies. Well for him who has a hobby, and best of all, one that entails some exercise of the mind, for intellectually it is impossible to stand still. We must go forward or backward.

Another advantage of our specialty is this, that when we leave our patients we leave our responsibility for them behind us. Not that our interest in them, either as patients or as human beings, need cease then. The time, short as it is, or should be, between the patient's arrival in the anæsthetic room and our putting him to sleep, is often an excellent introduction to an acquaintanceship which may ripen into friendship. He who has watched thousands of patients during this time cannot but have a feeling of admiration for the fortitude of human nature. What an ordeal it is for most of them, and how rarely does any one, grown up at least, show the white feather! In my own experience, the few who have refused to be operated upon, from fear, have been, almost without exception, men. There is, of course, the woman who turns her head away from the anæsthetic mask of face-piece, or puts up her hands to keep it off, but she only wishes to be coaxed. The quickest way to deal with her is to tell her that she is there of her own accord, that she is not obliged to have the operation if she does not want it. I have never known this expedient to fail.

Our admiration for human nature is somewhat qualified when we see women arrive in the anæsthetic room wearing wigs, or with their hair dyed, strange and pitiful evidence of vanity in those, who, in their efforts to deceive others, deceive only themselves. The rouging of lips and cheeks, however, is less easy to condone, for this, if artistically done, may add to our difficulties by disguising one of the most useful signs by which we estimate our patient's condition. With regard to children, I have come to believe that I can tell the character of a mother by the way her child behaves in the

anæsthetic room. When I am told that the patient is a "very nervous, high-strung child," I suspect that the mother is a fool. The child of a wise mother accepts the inevitable with the composure which comes of discipline.

I cannot help thinking sometimes that we might make the ordeal of an operation a little less trying to our patients than we do. The ideal arrangement for an operating-room suite would be to have a separate corridor leading to the anæsthetic room, so that the patient could not see his fellow sufferers on their way back to their rooms, bandaged, with air-ways in their mouths, perhaps retching, and perhaps with blood upon their faces. If they were prevented from getting a glimpse of nurses bustling about, or of a surgeon with a bloody gown washing his hands, they would be not a whit the worse. I would have the doors of the anæsthetic room sound-proof so that the noise of basins dropping on marble floors, or of the banging of lids of metal drums, would not reach the patient's ears just at the moment when the first few breaths of the anæsthetic have made his hearing painfully acute.

I am not, I know, suggesting anything new. I shall be told that these considerations have occurred to us all, and that the need for economy in space and money prevent such ideal arrangements. I reply that I am not convinced. Architects are still building fine new hospitals with anæsthetic rooms so small that they cannot be used. If it is possible to find money to waste in this way, surely it is possible to find a little more and invest it so as to bring a return in increased comfort for the patient. Curiously enough, anæsthetists are rarely, if ever, consulted in this matter. The surgeon is consulted, but he knows less than anyone else because he is there for only the briefest moments. When he is shown the plans of the new operating rooms for his hospital, and is told that they are based on those of St Basilisk's Hospital, where the famous Slasher clinic is, he is satisfied. He says he knows Freddy Slasher intimately, has been at his clinic, and has never heard him complain about his anæsthetic rooms. Thus mistakes are passed on from one modern hospital to another.

My ideal anæsthetic room would not look like a room in a hospital. There would be two or three pictures on the walls, and muslin curtains,

preferably not white ones, at the windows A carpet, of course, there could not be White enamelled furniture would be absent, and anæsthetic apparatus as inconspicuous as possible I know that a little extra work would fall upon the ward maid or orderly, and that visiting doctors would look surprised, and even shocked, but I believe that these drawbacks would be compensated for by the improved morale of the patients I know, too, that these aspirations of mine are vain I realize that in this efficient age, we are, in these matters, bound hand and foot by convention Hospital rooms must look like hospital rooms There is no point in being efficient if you do not look efficient And how repellantly efficient the inside of a modern hospital looks to a patient!

There is another way in which we might make things easier for our patients We might shorten the time during which they are under the influence of the anæsthetic We are all agreed that there is much unnecessary loss of time between the commencement of the anæsthetic and of the operation From the anæsthetist's point of view, surgeons may be divided into two classes In the first are those who are afraid of the effects of the anæsthetic on their patients This is a small class, made up chiefly of young, clever and ambitious surgeons who are not willing to lose a point, however small, in their patients' favour In the second are those whose confidence in their anæsthetist is so unbounded that they think it does not matter how long the patient is kept under the influence of the anæsthetic They are commonly seen washing up in a leisurely way after the patient has been ready in the operating room for some time The members of this class are almost without exception, men who have "arrived"

Not is it only before the operation begins that time is wasted The advantages of speed in operating have been rather overlooked It is astonishing how well the body can stand the trauma of a surgical operation if it be inflicted quickly Quickness in operating depends chiefly upon manual dexterity The quick operator is, like the poet, "born, not made" He has been endowed at his birth with clever hands The awkward man must educate his hands He may become a good operator but he will never become a quick one Two of the greatest surgeons

of the past, John Hunter and Lord Lister, belonged to this latter category One of the rarest combinations is that of a first-class brain with first-class hands There are many surgeons who have first-class hands, and excellent minds, who fall short of greatness because they have not sound judgment Then lack of balance leads them into adopting fads, and if they have a gift for publicity and organization, and are not handicapped by too much modesty, they become famous The first-class mind is, unfortunately, too often associated with second-class, or even third-class hands There is another point to which I should like to draw your attention before I leave this subject I think we shall find that clever hands are rarely well-shaped from an æsthetic point of view, and *vice versa*, that well-shaped hands are nearly always clumsy

The rarity of great surgeons is no cause for wonder It is a good deal to expect of a mere human being that he should have, not only the highest endowments of mind and hand, but the right sort of personality, and the sound physical health which is essential in the most exacting of professions Not often in one frail body do you find

"The reason firm, the temperate will,
Endurance, foresight, strength and skill"

One of the signs which distinguish the great surgeon in the operating room from his colleagues of smaller calibre is this—he knows when he has done enough, and stops He has either less faith in himself than they have, or more faith in nature I sometimes wonder if surgery is not passing through a phase which is characterized by a lack of confidence in nature's power to heal Is it necessary, for instance, to sew up the skin with such meticulous precision that there is not more than an eighth of an inch between each suture? Will not a cavity left in the mouth after an operation, heal properly unless packed with iodoform gauze? I have never experienced the taste and smell of iodoform and ether, combined with nausea and the discomfort which follows trauma in the mouth, all at the same time, but if I ever do, I think I shall spit out the iodoform gauze and take my chance with nature I make no excuse for holding these and other unorthodox opinions, because I have learned by dipping into books on the history of medicine that the progress of surgery has been

largely a process of discarding wrong old practices in favour of wrong new ones

I have recently been reading the highly entertaining preface to Bernard Shaw's "Doctor's Dilemma," and learning what villains we doctors are. "The medical profession," he says, "has not a high character, it has an infamous character." And again, "It is simply unscientific to allege or believe that doctors do not, under existing circumstances, perform unnecessary operations." Now, it is of course true that there are rascals in our profession, as there are in all other walks of life, and that there is a certain number of operations done from a mixture of unworthy motives, chief among which are the need of money, and the wish for practice or advertisement. But in large hospitals there is a powerful deterrent about which Bernard Shaw was ignorant, and that is the watchful eyes which are focussed on the surgeon when he is in the operating room. If he makes a mistake it is known in a few minutes all over the hospital. If there is a suspicion that he has operated without good reason every one knows, and no one gives him the benefit of the doubt. The light which shines upon his reputation is fiercely bright. The best antiseptic of the operating room is the criticism of colleagues, the wholesome influence of which is reinforced by the fear of public opinion as crystallized in the minds of remote beings known as "governors."

Bernard Shaw in the preface from which I have quoted asks the question "Are doctors scientific?" In unequivocal language he answers his own question in the negative. "As a matter of fact," he says, "the rank and file of doctors are no more scientific than their tailors." Whether we think Shaw right or wrong depends on what meaning we attach to the word "science." If we mean by "men of science" men who are intellectually honest, who want to find out the truth and to publish it stripped of all the obscurity which tradition, imagination, prejudice and self-interest throw over it, then I think we must be careful how we pride ourselves on being scientific. It is because we do not vitally care whether we have truth itself served up to us, or error dressed up to look more or less like truth, that medical literature in journals and books has attained its present monstrous proportions. In spite

of our training in science ours is the most credulous of professions.

A year or two ago I read in a leading French medical journal an address given by one of the most famous surgeons in Europe upon the subject of general anaesthesia by the spinal injection of stovaine. For twenty years he had used this method of anaesthesia to the exclusion of all others, in every kind of operation in general surgery. "sans accident, sans mortalité." Now, having had a fairly wide experience of general and spinal anaesthesia, I confess I was a little incredulous. Could anyone I asked myself, carry on a large surgical practice for twenty years, and never have an "accident" or a death on the table? If he had had such a death or an accident could he be quite sure, in view of the fact that he was using the spinal injection of stovaine for general anaesthesia, that the anaesthetic played no part in it? It was a good deal to ask one to believe. But what sort of anaesthesia did he get? On this point I received enlightenment from a friend who had seen the great man operate upon a patient with cancer of the breast. "The patient," he said, "suffered a great deal of pain during the operation."

Here is another example of the truth which is not the whole truth. A distinguished surgeon and teacher of surgery some years ago operated within the space of a month or two upon four patients, who by reason of intemperate habits, obesity, and disease of the lungs were considered unsuitable for general anaesthesia. Three of them were given a spinal anaesthetic and made excellent recoveries. An attempt was made to give the fourth a spinal injection but resulted in failure owing to the impossibility of introducing the needle into the subdural space. He was then given ether and made as good a recovery as any of the other three. Now the surgeon reported the first three cases and said nothing about the fourth although his paper was written to show the place of spinal anaesthesia in certain operations where general anaesthesia is contraindicated.

Had Bernard Shaw thought of turning to medical writings for evidence to support his statement that we are no more scientific than our tailors I am afraid he would not have had to search far. He would have found it in the slipshod use of language which has unfortun-

ately become so common, and which can arise from no other cause than slovenly ways of thinking. As an example of what I mean I shall quote the following sentence which is taken from an article written by a member of the surgical staff of one of the great clinics of North America: "The consideration of operation in the presence of the degenerative cardiac diseases must be individualized and based entirely on the prognosis of the particular type of disease as ascertained by clinical and electrocardiographic studies, considered in conjunction with the urgency of the operation and the effect on the cardio-vascular system of removal of the surgical burden." Now, what I ask is all this about? The use of the word "individualized" I find especially confusing. I looked up the word in the dictionary, and found that it means, "to give individual character to, to specify," and I wondered how one can individualize a consideration.

Another example comes, I regret to say from a paper written by an anesthetist. "Respiration during induction," he writes, "may terminate in apnoea even though they (the patients) are still too light to initiate surgical procedure." Passing over the colloquial sense in which the word "light" is used, we have here a statement from which we are justified in inferring that when the patients are more deeply under the influence of ether they will begin to operate upon themselves.

I have never heard any plausible explanation of the confusion of tongues which put a stop to the building of the Tower of Babel. My own theory is that everyone employed upon that work adopted the position of Humpty Dumpty in "Through the Looking-Glass." "When I use a word," said that bold philologist, "it means just what I choose it to mean, neither more nor less."

In this same spirit we have dealt with the

word "pathology." Originally it meant, if we may judge by its derivation, "a discourse on disease." It is now also a synonym for "disease." A patient with bronchitis has "lung pathology." To realize fully how confusing is this sort of innovation we have only to subject other words ending in "ology" to the same treatment. Theology becomes a synonym for God, and the Revised Prayer Book of the future will contain a creed commencing with "I believe in theology." An atheist will be one who "does not believe in theology." "Phienology" will come to mean "mind," and a madman will be one who has "gone out of his phienology." If by the time he recovers, the word "physiology" has acquired the meaning of "health," he will be said to have recovered his "phienological physiology." Shall we be justified in feeling sorry for him if he relapses?

It is no excuse for writing carelessly to plead that one has not time to do better. Readers do not hear the excuse. What is badly expressed they find difficult to understand, and will not bother to read. "If your language is jargon," says a great modern teacher, "your intellect, if not your whole character, will almost certainly correspond. Where your mind should go straight, it will dodge, the difficulties it should approach with a fair front, and grip with a firm hand, it will be seeking to evade or encumbrance. For the Style is the Man, and where a man's treasure is, there his heart, and his brain, and his writing, will be also."

There are several other subjects about which I should like to speak, but I refrain out of consideration for the feelings of the gentlemen who have arranged the program of this meeting. I know that to them long-windedness is the unpardonable sin. I hope I have not offended too deeply.

A Medical Family—In August, 1828, Matthew Baillie Gairdner became a licentiate of the Royal College of Surgeons of Edinburgh, at the early age of 19, he graduated M.D. at the University of Edinburgh two years later, and became F.R.C.S. Ed. in 1858, he died in 1888. His eldest son, James, graduated M.B., C.M. Ed. in 1867, proceeded M.D. in 1873, and has acted as medical officer of Crieff Parish in Perthshire for more than sixty years. The professional practice of father and son has thus

covered more than a century. It would be interesting to know if this record can be approached by any other medical family. Dr. James Gairdner's younger brother, Matthew William Gairdner, graduated M.B. Ed. and obtained the diploma of L.R.C.S. Ed. in 1871, he resides at Cheltenham, and his son, Alan Campbell Gairdner, is a medical graduate of Oxford and obtained the F.R.C.S. Eng. this summer.—*Brit. M. J.*, 1928, II, 583.

An Address ON THE FIELD OF NEUROSURGERY*

By WILDER PENFIELD, M.D., B.Sc. (Oxon.),

Clinical Professor of Neurosurgery, McGill University, Montreal

THE differences between the American and Canadian medical profession have little to do with science and much with tradition and background. For me, to leave the one and enter the other is made easier by years of medical study in Great Britain, and because of the fact that I can claim as my teacher and friend, a great Canadian, Sir William Osler.

Such a change is apt to cause one to look questioningly at the divisions between the ever more specialized branches of our profession. New knowledge, and a multitude of new technical procedures, have made it impossible for any man to master all of the intricacies of medical science, even though he were endowed with the many-sided capacity of Leonardo Da Vinci, or John Hunter. But a fair and efficient adjustment even between medicine and surgery, has long offered difficulty. It is my desire to speak briefly of this relationship, at least in so far as it concerns the treatment of diseases of the nervous system.

Neurosurgery is perhaps the youngest of medical specialties. Operations upon the central nervous system were naturally doomed to failure until Lister had given us the secret of the control of sepsis, and Ferrier had provided the clue to localization of function in the brain, for sepsis within the meninges spells death and blind exploration may mean paralysis.

Neurologists who early saw the goal to be attained called upon surgeons who did not understand the goal and who were ignorant of the physiology of the nervous system. The results were terrible and the profession gradually concluded that the unfortunate patients might as well be allowed to die in their own way. This attitude, which can be dispelled only by demonstrated results, lingers still in many localities.

Effective neurosurgery may be said to begin

with Sir Victor Horsley. He started his professional career as a surgeon but before he began his work upon the human nervous system he had made of himself a neurophysiologist, and years of experimental surgery had enabled him to develop a technique for such operations. With his use of bone wax, heat, and bits of muscle for hæmostasis, and his daring approach to all regions of the brain and spinal cord Horsley was a pioneer, and must always be considered the great figure in neurosurgery. MacEwen of Glasgow, at about the same time demonstrated the proper treatment of abscesses of the brain, and left behind him an almost unbelievably low mortality record in the treatment of this affliction.

Following Horsley, Cushing has refined the methods of neurosurgery and has demonstrated once and for all that these operations may be done with a low mortality by a specialized team. In his clinic it was first proved that simple craniotomy could be done with little more risk than that involved in celiotomy. Dr. Cushing's statistics have turned a new page in the surgery of tumours of the brain and hypophysis and there are a score of his pupils scattered through America and Europe, restricting their work to this type of surgery and reproducing his results according to their several ability.

In Philadelphia the fortunately combined efforts of a neurologist, Dr. Spiller, and a neurosurgeon, Dr. Frazier, have provided us with a permanent cure for trigeminal neuralgia by differential section of the posterior root, a procedure which, in experienced hands, has practically no operative mortality. They have also given us another means of liberating patients from unbearable pain, *i.e.* chordotomy, or section of the tracts which conduct pain in the spinal cord.

Dandy has provided us with a new method of cerebral localization, *i.e.*, roentgenography of the cranial cavity after direct ventricular re-

* Delivered before the Montreal Medico Chirurgical Society, November 2, 1928

placement of fluid by air or after similar spinal replacement. Thanks to this method, which should, however, be used only in doubtful cases, the diagnosis of unlocalized brain tumour is now practically never justified.

Such injections of air into the spinal canal may also be used as a specific cure for traumatic meningeal headache. There are many more advances in the field of the central nervous system and also the peripheral and sympathetic nervous system which may not be mentioned here.

Thanks to peculiar conditions in American professional and university life it has been possible for an ever increasing group of men to confine their activity to neurosurgery. The result has been a rapid expansion of this specialty. In one western city of the United States there are at present seven neurosurgeons, only one of whom is dependent upon a university budget for his income.

On the continent of Europe on the other hand, there has been no such specialization. Every general surgeon has held himself ready to do any operation upon the nervous system which may, by chance, be entrusted to him. The result has been little or no advance in surgical therapy. At the same time neurology on the continent seems to have failed to fulfill the brilliant promise of such clinicians as Marie, Déjerine and Oppenheim. The university chairs created for combined neurology and psychiatry have come gradually to be occupied by men whose interest is largely psychiatry.

In two neurological clinics, however, which are perhaps the most distinguished on the continent to-day, a new stand has been taken. Foerster, Professor of Neurology in Breslau, now carries out all of his own operations, and has become the leading and almost the only neurosurgeon in Germany. Brouwer, of Amsterdam, has induced his native city to send one of his assistants abroad for training in neurosurgery that he may return and operate within the university neurological clinic.

The future of neurology and the future of neurosurgery alike demand that these two specialties be combined in one. Herein lies salvation and guidance for both. A surgeon who operates upon the nervous system without

studying both the subject of neurology in general, and the neurological problems of his patient in particular, works under too great a handicap, regardless of his manual dexterity. The prerequisite training is similar for neurology and neurosurgery, and neither can do without the other. It is true that not every neurologist is in a position to operate, and likewise the surgeon who may spend two to five hours upon his feet in each major operation finds it quite impossible to treat non-operative neurological cases. There must be a professional subdivision of the material treated.

The neuropathological, neurophysiological, and clinical interests of medicine and surgery must be identical. The common meeting ground is above all the neuropathological laboratory. Comparative segregation of neurology and neurosurgery with their own methods of research and study is the *sine qua non* of future advance.

On the other hand, it is true that too great specialization is dangerous, and neurology and neurosurgery need the steadying influence of an association with general medicine and surgery, which should be as intimate as hospital life will permit. Aside from the clinic, the closest contact which this double specialty makes with surgery is through the operating room, with medicine through the research laboratory.

The field of neurosurgery, both now and in the future, should not be confined to tumours of the nervous system and the douloureux, as is the case in some clinics. On the contrary, it should include the prevention and the cure of traumatic epilepsy, control of cardiovascular pain and of intractable pain of all types, traumatic headaches and some types of migraine, birth hæmorrhage and the ensuing epilepsy, peripheral nerve injuries, and even some cases of pyogenic meningitis and hydrocephalus. These and other involvements of the nervous system open up a wide and much neglected field of activity.

The future promises much. New methods will surely solve many of the unsolved problems. In no other department of medicine is the need for new work more challenging, and in my opinion nowhere else is the discovery of scientific gold so certain.

ULCERATIVE COLITIS*

By P. H. T. THORLAKSON, M.D., C.M., M.R.C.S.

*Lecturer in Clinical Surgery, Medical Faculty, University of Manitoba,
Surgeon, Out-Patient Department, Winnipeg General Hospital,
Winnipeg*

THE subject of ulcerative colitis has received a great deal of attention in the medical literature of all countries during the past decade. In reviewing the English, German, French and American literature on this disease, one is struck by the similarity of the articles. It seems obvious that these writers from various countries are all dealing with the same condition and not, as has been suggested, with different diseases brought under the same name—ulcerative colitis. The term is undoubtedly unsatisfactory from the etiological standpoint, but the condition has been so adequately described, both in regard to its pathology and clinical manifestations, that no confusion should exist regarding the condition it is intended to designate.

One can summarize the present state of our knowledge of the disease in this way. Ulcerative colitis is a disease which is essentially chronic, but is subject to acute or sub-acute exacerbations. The exact etiological factor is unknown though it is almost universally agreed that it is an infectious disease of which the specific micro-organism has not been definitely isolated. The pathological lesion is typical and constant, being an erosion involving only the superficial layers of the mucosa in the earlier stages, but associated with oedema, congestion, and leucocytic infiltration of the entire bowel wall in the more advanced cases. While the whole length of the large bowel is frequently involved, the brunt of the disease is carried by the rectum and sigmoid. The clinical manifestations are diarrhoea with from six to thirty stools a day, which contain blood, pus, and mucus. A varying degree of secondary anaemia is always present. Loss of weight, in spite of a fairly good appetite, a slight temperature, leucocytosis, and cramp-like abdominal pain relieved by evacuations, are symptoms of minor diagnostic value. The sig-

moidoscope is indispensable in arriving at a correct diagnosis. The X-ray assists in the diagnosis by excluding other causes of diarrhoea, it also helps to determine the extent of the disease. It shows hypermotility of the colon with absence of normal haustrations, the typical pipe-stem or ribbon-like colon. (See Fig. 1)

Finally, the treatment is not standardized, owing to the fact that we do not know the exact micro-organism with which we are contending, but in spite of this serious handicap the results from active and thorough treatment carried over a period of months in every case are on the whole quite satisfactory.

BACTERIOLOGY

In discussing the possible etiology of this disease, mention must first be made of Baigen's work which constitutes a noteworthy contribution to the study of this malady. Future advances in our knowledge of the disease will perhaps depend entirely upon bacteriological research. Baigen has described a non-mannite fermenting diplococcus which he considers to be the causative agent. He has been able to isolate this organism in about 75 per cent of his cases, and has noticed an improvement from vaccine therapy. At first this seemed most encouraging, but our experience during the past year has not been such as to make us feel that this was the solution of the problem. In one of my cases, I was able to obtain a fairly pure culture of this diplococcus from a superficial smear taken from the rectal ulcers and an organism morphologically similar from an abscessed tooth. This patient showed a marked improvement after extraction of the affected tooth and a repeated course of vaccine, but it is difficult to be sure which was chiefly responsible for this improvement. She has had very thorough treatment with the diplococcus vaccine, but has had relapses and is far from well. From clinical ob-

* Read before the Canadian Medical Association, Charlottetown, P.E.I., June 21, 1928.

servation and the result of bacteriological work, I have come to believe that this diplococcus is not specific for the disease, but is only one of the predominating secondary infective organisms. The bacteriological studies carried out by Paulson at the Johns Hopkins Hospital support this view.

FIG 1—Ulcerative colitis—typical pipestem colon

I have been making careful bacteriological studies of our cases for more than two years, but it occurred to me only about six months ago that there was an obvious explanation for the different results obtained from other places. Bergen and others have used sterile cotton swabs to obtain their specimens, whereas I have been using a sharp cutting curette with a very small spoon and a long handle. In this way I obtain a small section of the base of the ulcer and not merely a surface smear. Text-books on tropical medicine tell us that the dysentery bacilli will often disappear from the stool within ten days after the onset of the disease, but that the organism can be obtained later from sections of the bowel wall. It has occurred to me that this is the reason why Dr F Cadham has been able to isolate the dysentery bacillus from our scrapings. He has reported *Bacillus dysenteriae* present in four of the last five cases in-

vestigated. Three cases belonged to the Flexner group, whereas the fourth was of the Shiga type.

One of my cases who had the diplococcus vaccine at different intervals for more than a year, without improvement, was later treated by caecostomy with routine irrigations and by serum therapy. The serum was prepared by Dr F Cadham of the Manitoba University and produced the most gratifying results. From being markedly anæmic the patient's blood count has become normal, and his bowel movements have been reduced from twelve to sixteen to one or two evacuations a day.

PREDISPOSING FACTORS

Very little importance can be placed on so-called predisposing factors. It must be admitted that many persons are exposed to this infection who do not develop ulcerative colitis. Others again contract the disease and make a complete recovery without special treatment. When we speak about a patient's constitutional predisposition or his resistance to infection these are only phrases the exact meaning of which is not known.

DIAGNOSIS

Other causes of diarrhoeas, such as tuberculosis, malignancy, systemic manifestations of chemical poisons, and achilia gastrica need only be mentioned. Some of our cases had been treated as tuberculous colitis for varying periods before coming under our observation. The differentiation is extremely easy. Blood is never a feature in tuberculosis of the bowel, and when it does occur is usually due to an associated lesion, such as hæmorrhoids or polypi, in ulcerative colitis hæmorrhagic stools are a constant feature. Then, again, sigmoidoscopic examination of the rectum and sigmoid is usually quite negative in tuberculous disease, whereas in ulcerative colitis the typical lesion as described can nearly always be seen. There are some cases where the disease is confined to the transverse or descending colon and sigmoidoscopic examination has been negative, but even in these cases the rectum becomes involved in time. (See Fig 2). A negative sigmoidoscopic examination, therefore, does not invariably exclude ulcerative colitis. In these cases the x-ray becomes essential for diagnosis. A barium series and a barium enema

FIG 2—Illustrating a localized area of ulceration in the transverse colon which later became generalized

should always be done to determine the extent of the ulcerative process, and also to determine the presence or absence of simple strictures or filling defects which might indicate malignant disease. A gastric analysis should always be made as the cases with achlorhydria are often helped by the administration of hydrochloric acid.

During the period of natural remissions which occur in some cases, investigation of the stool will continue to show the presence of blood and pus, and sigmoidoscopic examination will reveal unhealthy mucosa which is oedematous and studded here and there with minute ulcers (latent colitis).

COMPLICATIONS

The complications seen are (1) arthritis, (2) hæmorrhage, (3) perianal abscess, (4) stricture, (5) polyposis, (6) perforation, (7) malignancy. (See Fig 3)

TREATMENT

Contrary to the experience of many writers on the subject, we have found a simple cæcostomy for purposes of irrigation of inestimable value. A soft catheter is purse-stringed into the

FIG 3—Ulcerative colitis of seventeen years' standing complicated by malignancy of the transverse colon

cæcum. This can usually be done under local anaesthesia and carries with it practically no risk. The appendix is usually removed at the same time. We have instituted continuous irrigation in some of our severe cases, thereby giving instant relief to the patient from the distressing tenesmus and frequent evacuations. An ordinary irrigating-can with Murphy's drip attachment, is connected to the cæcostomy tube and warm normal saline allowed to enter by a rapid-drip method. At the same time a small rectal tube is inserted and connected to a large vessel under the bed. By this means the cæcum and ascending colon are intermittently filled up with warm solution which is then flushed through the remainder of the large gut.

Normal saline solution is the best suited for this type of irrigation. Tannin, silver nitrate, and such-like irritants should probably never be used. By means of the irrigation a cleansing of the ulcerated surface is accomplished and prevents to a large degree the absorption of septic products.

A transverse ileostomy (Brown's operation) is rarely necessary, but finds its usefulness in selected cases. Indications for this procedure are (1) repeated profuse colonic hæmorrhages,

(2) generalized polyposis, and (3) in long standing cases where the colon has been converted into a useless, fibrous tube. It is not indicated in the acute early cases, as these can be controlled, with few exceptions, by hot irrigations through a small caecostomy tube. In one of my cases, with profuse repeated hæmorrhages requiring transfusion, I did a transverse ileostomy under local anaesthesia, employing the principle advocated by Mikulicz in his operation on the sigmoid for carcinoma. The ileum was double-bagged about twelve to sixteen inches from the caecum along the antimesenteric surface for about three inches. This portion was returned to the abdomen and a rubber tube placed under the loop. Nine months later, when it was desired to re-establish the continuity of the intestinal tract, a crushing forceps was applied to this spur and within five days the patient was having normal bowel evacuations. The advantages of this extra-peritoneal anastomosis is obvious in a debilitated patient. Dr N J Maclean has used this technique with gratifying results in cases of tumour of the small bowel and gangrene of the ileum with obstruction, when immediate anastomosis would undoubtedly have proved fatal.

The dietetic and medical management is important both during and following active treatment. A low-residue diet of high caloric value is indicated. Cod liver oil and calcium lactate by the mouth may be added. Stovarsol occasionally produces a spectacular improvement, but in these cases I suspect an associated amœbic infection. The drug must be used very cautiously, as some patients have an idiosyncrasy to it.

Finally, it should be recorded that we are using at present an autogenous serum prepared by Dr F Cadham. The serum is obtained by injecting into animals the Flexner bacillus

isolated from recent cases. Nothing conclusive can be stated at this time, but it is likely to prove a distinct advance over other methods of treatment. This work requires experimental confirmation.

Personally, I feel that the final solution of primary ulcerative colitis will not be medical, surgical, nor vaccine therapy, but that serum therapy will eventually cure the disease.

SUMMARY

- 1 A new method of obtaining specimens for bacteriological studies is presented.
- 2 The advantages of a modification of the usual transverse ileostomy are mentioned.
- 3 A new advance in treatment by serological methods is indicated (autogenous serum).
- 4 Ulcerative colitis, according to our observations, is due to infection with *Bacillus dysenteriae*, and should be regarded as a form of bacillary dysentery.

The July issue of the *Kenya and East African Medical Journal* contains a report of an investigation into animal nutrition in Kenya, the supervision of which was undertaken by Dr J B Orr, director of the Rowett Research Institute, Aberdeen. One conclusion reached was that, in areas where the pasture is deficient in minerals, an increased rate of growth in lambs and

calves, and a better yield of milk in cows, can be obtained by feeding with appropriate mineral mixtures. The issue also contains an article on the control of bilharzia disease, by Dr F G Cawston, and an account by Dr A R Paterson of the organization of anti malarial work in the Federated Malay States.

DEPILATION WITH THALLIUM ACETATE IN THE TREATMENT OF RINGWORM OF THE SCALP IN CHILDREN*

By GEORGE V. BEDFORD, M.D.,

*Physician in Charge Skin Clinic St. Boniface Hospital,
Demonstrator in Dermatology, University of Manitoba,*

Winnipeg

UNTIL thirty years ago the treatment of tinea capitis, or tinea tonsurans, was most unsatisfactory. Local applications of tincture of iodine, croton oil, and ointments containing ammoniated mercury, oleate of copper, sulphur, resorcin, salicylic acid, etc., were the usual remedies. Such treatment was tedious and usually lasted many months. The great difficulty in local therapy was the mechanical impossibility of reaching the fungi in the hair follicles. About the middle of the last century, institutions called "ringworm schools" were established in London and Paris. The average residence of patients was eighteen months for the common small-spored fungus cases, but some of the large-spored infections took three years to clean up. The economic importance of the disease is thus easily seen.

A tremendous advance in therapy took place when x-rays were found to cause depilation. Freund was the first to suggest their use. About the same time Sabouraud, of the Hôpital St. Louis in Paris, first used them in the treatment of ringworm of the scalp. MacKee¹ tells us that in 1904 Sabouraud and Nolle devised a method of depilating the scalp at one sitting. Since that time this treatment has come into general use. The x-rays cause depilation by some imperfectly understood action on the hair follicles. They have no direct effect on the fungus. When the hair falls the organisms are removed with it from the follicles. Any that remain may be reached by mild fungicidal applications.

Felden² tells us that in 1897 Sabouraud observed a patient who had lost almost all her hair after taking some pills prescribed for dysentery. He found on investigation that a number of these pills contained thallium acetate.

After a few weeks the hair was restored completely. This suggested the use of the drug therapeutically but, after seeing some toxic symptoms, he gave it up and later returned to depilation with x-rays. Buschke, of Berlin, should be credited with really demonstrating the practical usefulness and chemical value of thallium acetate therapy in tinea capitis.

The therapeutic value of the treatment has been thoroughly tested in recent years. Drummond³ states that Cicero and Peter, of Mexico City, have used the method in more than 500 cases with good results. About 1,000 cases were reported in 1926. Very little of this work was done in England until last year when Dowling,⁴ Firth,⁵ Dixon,⁶ Curtis,⁷ and others reported a series of cases.

During the past nine months 21 cases, 17 of tinea microsporum and four of favus capitis have

FIG. 1—A case of tinea capitis before treatment.

* Read at a meeting of the Winnipeg Medical Society, Winnipeg, Man., Sept. 20, 1928.

been treated in St Boniface Hospital Skin Clinic by thallium acetate. Three of the favus patients had been treated with rays unsuccessfully before coming to St Boniface. Two of the twenty-one children are still under treatment.

The technique has been as follows. After a general examination in the paediatric clinic, the child is carefully weighed without any clothes. Thallium acetate is accurately prescribed in a dosage of grs $\frac{1}{8}$ (8 mg) per $2\frac{1}{4}$ lbs (1 kilo) body weight. The drug is administered in a single dose in half a glass of sweetened water first thing in the morning and no food is given until noon. From the first day a fungicidal ointment, ammoniated mercury (2 per cent), or sulphur (5 per cent), is applied night and morning to the scalp. There is also a daily shampoo with liquid green soap. About the twelfth or fourteenth day, the hair begins to loosen and adhesive tape is used to assist in depilation, which is usually completed about the twenty-first day.

falls. This is essential as a protection to the new hairs against infection.

There has been a good deal in the literature about the toxic effects of this drug. The commonest symptoms reported are joint and muscle pains, nearly always in the lower limbs. These

FIG 4—A case of favus before treatment.

FIG 2—Complete depilation after the use of thallium

FIG 5—Complete depilation after the use of thallium.

FIG 3—Growth of hair two months later

Re-growth after thallium depilation begins very early. We have observed it after one week in some of our cases. Because of this it is most important that the shampooing and daily application of a mild antiseptic ointment should be kept up for at least one month after the hair

FIG 6—The same case three months later

pains generally begin about a week or ten days after the taking of the drug. Loss of appetite, drowsiness, and irritability have been noted. In our series we have had three children with toxic symptoms. One boy almost thirteen years of age was confined to bed for two weeks because of pain, swelling and restriction of movement in both knees and both ankle joints. He cleared up with rest and the administration of salicylates. One girl of ten had loss of appetite, with pain and swelling in the right knee. One week's rest in bed restored her to normal. Another boy, eight years old, complained of pain in both legs, but after three days in bed he recovered completely. We had one complete failure in a boy of ten with stout, coarse hair, one partial failure in a seven-year old girl, and another partial failure in a six-year old boy.

Pusey⁸ informs us that Buschke summarizes the advantages of thallium acetate therapy as follows —

(1) The treatment is extremely simple and

costs almost nothing (2) It can be used for children under three years of age (3) It can be used in country districts where x-rays are not available (4) It can be used for cases where x-rays have proved unsuccessful (5) It may be used for cases of inflamed ringworm (kerion) (6) There is no danger whatever of permanent alopecia

The disadvantages are (1) Its toxic effects (2) It is not so certain to cure as a good x-ray depilation, though this difficulty may, he thinks, be overcome by very careful local treatment

CONCLUSION

1 In our opinion the method of prescribing the drug is important. Two of our failures were due to under-dosage. Once the drug was dispensed in an ordinary powder paper and as it was a sultry day the paper absorbed part of the drug, another time a gelatine capsule was used and as this was dispensed on a very hot day the capsule appeared to melt and some of the drug escaped and was absorbed by the wrapper. Thallium acetate is very soluble in water and in humid atmospheres tends to deliquesce. Our experience has taught us to use a glass vial as a container.

2 Our limited experience has shown the value of this form of therapy, in feeble minded children, in kerion (inflamed ringworm), and particularly in favus capitis. The latter responded to treatment very satisfactorily.

3 We believe that treatment by thallium acetate marks a real advance and will be welcomed particularly by the rural practitioners in this country. It must be borne in mind that toxic symptoms are likely to occur in children approaching puberty.

PHARMACOLOGICAL AND TOXICOLOGICAL ASPECTS OF THALLIUM

BY M J ORMEROD, M B,

*Assistant Professor of Physiology and Pharmacology, University of Manitoba,**Winnipeg*

ALTHOUGH thallium was detected spectroscopically by Sir Wm Crookes in 1861, and investigated chemically by Lamy in 1863, it was not introduced into therapeutics until about thirty-five years later. Its first employment was to check the night-sweats of tuberculosis. 5-10 mgm per day of the acetate was a common dose. The anhidrotic action continued only while the drug was being taken. After the drug was discontinued a curious patchy baldness occasionally ensued. Sabouraud (1897) and Richet (1899)¹ demonstrated this as a specific thallium effect, and the former used the drug in the form of a 10 per cent salve as a depilatory in the treatment of scalp ringworm. Depilation followed some weeks after the salve was first applied, apparently indicating an action only after absorption rather than a local effect. Toxic symptoms, such as enteritis, albuminuria, and œdema, occurred so frequently that he discontinued the use of the drug.²

In 1900, Buschke in Germany commenced an experimental study of the drug, and most of the literature to-day is the result of his prolific pen. He has experimented with animals from the tadpole to the ape, and many interesting results are reported. Tadpoles immersed in dilute thallium solutions fail to grow or continue development.³ Rats fed on thallium develop bone changes histologically identical with rickets or osteomalacia.⁴ Old rats lost the sexual instinct, young rats suffered atrophy of the testicles, very young rats developed cataract.² The adrenal bodies, post-mortem, showed vacuolation and deficiency of epinephrin content.² All these effects Buschke attributed to a severe endocrine disturbance. The falling of hair was, of course, a conspicuous effect in all his experiments. A curious fact was that the long sensory hairs on the rat's nose were not affected by thallium. In work on human beings, it was found that nostril-hairs, eyelashes, inner parts of the eyebrows, and, where present, hairs in moles, also remained

fast while all other hair fell out.⁵ Buschke therefore assumed that, since the sympathetic nervous system is closely associated with the endocrines, there was a sympathetic effect here, and that all hair which fell out was innervated by the sympathetic system, all that remained firm was otherwise innervated. This, of course, is pure theory, since no microscopic work has been done to support it. Thallium's action in suppressing the secretion of sweat suggested that it might be antagonistic to pilocarpine. Experiments showed that pilocarpine's action is not affected by thallium, and Buschke states that such action as thallium has is exerted centrally and not peripherally on the nervous system.⁵

At a meeting of the Royal Society of Medicine in 1927, Dixon⁶ reported his observations on the action of the drug. His researches indicate an effect on the nerve ganglion or synapse, in that impulses pass through much more easily, especially in the sympathetic system, after the use of thallium. The immediate effect of the injection is a relaxation of all smooth muscle, suggesting a possible augmented sympathetic action. Depilation occurs after two weeks. A curious exhibit was a picture of a rat with a small shaved area on the back, fed on thallium, and finally presenting the picture of complete baldness with the exception of the shaved area, in which a luxuriant growth of hair had occurred. In many investigators' reports is noted the richness of re-growth of hair after thallium. Histological examination of skin and hair in the areas of alopecia has shown no considerable or permanent change in the hair follicle, except in the case of prolonged thallium feeding, when atrophy does occur.

While there are records of hundreds of successful treatments, there are a few reports of thallium poisoning available also. Swan and Bateman (1910),⁷ injected several animals with thallium salts. The main facts brought out by them are (1) in large doses thallium acts much

like lead or arsenic, (2) the action of thallium is cumulative, (3) early involvements of the central nervous system (apathy, tremor, paralyses) and of the kidney (albuminuria, diuresis) are characteristic. Pauchly, (1926)² reports three cases with a mildly toxic reaction in a series of fourteen cases treated; all three showed transient albuminuria and glycosuria. Davies and Andrews, (1927)³ report a case where two sisters, aged eight and eleven, received doses of 85 mgm per kg, of thallium acetate. The younger felt no ill effects whatever and depilation was satisfactory. The older sister reported in two weeks, just after the hair commenced falling, with marked and painful oedema of the legs, swelling of the knees, and pain in both knee-joints. Symptomatic treatment was given. Two days later the child's parents reported that she had had a fit epileptiform by the description and had then been semi-conscious for two hours. Frequency of urination followed (every half-hour for several hours). The only pathological substance in the urine was acetone which persisted for several days in spite of a high carbohydrate diet. Five weeks after taking the drug the child was discharged from hospital emaciated with some tenderness of legs, but able to walk, and suffering from occasional attacks of lethargy and oedema of the face lasting fifteen minutes. In commenting, the authors speak of arthritis and peri-arthritis of the knee-joint "with which we are familiar as occurring *nearly invariably* to a lesser degree." Other therapists noted severe nerve and muscle pains as being frequently associated with thallium treatment.

Two suicidal (unsuccessful) cases reported in Germany^{9, 10} (doses of about 10 mgm per kg in adults) indicate toxic action as mainly (1) violent gastro-intestinal upset (anorexia, vomiting, diarrhoea, constipation, achilorrhoea, colic), (2) peripheral polyneuritis, (3) transient kidney disturbances, (4) cessation of menses, (5) early lymphocytosis followed by eosinophilia (endocrine disturbances are frequently associated with eosinophilia). Four weeks after taking the drug, thallium was still demonstrable in the blood and urine, and blood-calcium and potassium values were then normal. No previous determinations had been made.

A homicidal (successful) case is also reported¹¹. A brand of rat-poison containing about 3

per cent of thallium salts was the agent employed by the wife against her spouse. After a six-weeks' stay in hospital, with much the same symptoms as above, the man was well enough to go home, but a second poisoning led to his death in three weeks. An incomplete report¹² of perfusion of a frog-heart with a solution containing thallium states that after a few beats the heart stopped in diastole. The addition of calcium salts to the fluid resulted in a prompt resumption of the beat.

Efforts to avoid toxic symptoms by a combined therapy of a half-dose of thallium and a half-dose of X-ray have received favourable mention by some but results are not so uniformly successful as with thallium alone. The combination of thallium and X-ray or radium therapy has been successful in treating two cases of epithelioma which were resistant to radiation alone.⁹ Apparently there is some common basis of explanation of thallium and X-ray action in this matter but as yet it remains a mystery.

Post-mortem analyses of body-structures show that the muscles act as the main storehouse for thallium.⁹ The analysis of skin and hair fails to show thallium in these structures so that local action does not appear to be the clue. Excretion is mainly by the kidney, but thallium may be detected in all the body secretions after feeding the drug. It is readily excreted in milk and experimental evidence is present to show that the fetus is poisoned by feeding thallium to the mother.¹² Buschke believes this may be an indirect effect, through malfunction of the endocrine glands.

SUMMARY

From this array of clinical and experimental evidence a few points may be extracted.

1 Young children up to seven or eight years of age withstand thallium well, older children and adults are more likely to show toxic symptoms.

2 Evidence is offered of various endocrine disturbances during the use of thallium. Whether these are directly due to the drug cannot be stated definitely.

3 Evidence of disturbed metabolism especially calcium deficiency, is presented. The muscle cramps could be correctly explained by a removal or antagonism of calcium by thallium. Oedema, diuresis, etc., may be due to increased

capillary permeability, which occurs in calcium deficiency. Disturbances of the central nervous system, such as fits or tremors or apathy, occur where calcium metabolism is upset, as in injury to the parathyroids. Osteomalacia and rickets are definitely due to calcium deficiency. Whether such calcium disturbance is caused directly, or is secondary to parathyroid damage, is a matter for further investigation.

4 Nerve damage does not appear to be permanent. Kidney damage also appears to be transient, if the kidney is damaged at all.

5 No permanent damage to the hair-follicle results from therapeutic doses of thallium salts.

6 Since the action of thallium is cumulative, it seems that some toxic effects must be endured for the sake of the therapeutic benefits, and drugs to increase elimination, such as sodium thiosulphate, are contraindicated.

7 No observers, clinical or experimental, have followed cases for a sufficiently long period to

say definitely whether or not permanent damage may follow such chemical or endocrine upsets, particularly in view of the fact that most of the patients are growing children.

Some research into thallium has already been done by our department, and further work is being carried on now, in order to clarify some of the problems set forth in this paper.

NEPHROSIS IN CHILDREN*†

By GLADYS L. BOYD, M.D.,

Toronto

III. COURSE, PROGNOSIS AND TREATMENT

THE insidiousness of the onset of nephrosis is one of its characteristic features in most of the cases. Weeks, or even months, of vague ill-health, pallor and lassitude are succeeded by a gain in weight, which at first is regarded as improvement. Such increases in weight may come and go several times before their true nature becomes manifest and œdema is demonstrable. Subsequently, the hydropic state develops rapidly and in a few days general œdema and anasarca may be present to an extreme degree. More rarely, the development of the dropsical state follows an acute upper respiratory infection in a previously healthy child. Less frequent still are those cases in which uræmic

symptoms due to cerebral œdema usher in the disease. Such cases do not always present any marked degree of general œdema, this may be limited to that of the cerebrum and the external genitals.

The mode of onset exerts considerable influence on the subsequent course of the illness. Those cases in which the onset is sudden, particularly those with cerebral œdema, usually run a more or less acute course for some weeks, and then all signs and symptoms of the disease disappear. In cases in which the disease is more gradual in its development, recovery is likewise slow, if indeed it occurs at all. In those in which the disease becomes chronic, months of invalidism, during which gross œdema recurs again and again, or persists over long periods, may be ultimately followed by cure or terminated by an intercurrent infection. More rarely, as pointed out in a previous paper,¹ chronicity may produce secondary changes in the kidney which

* From the Laboratories of the Sub Department of Pediatrics, University of Toronto, and from the wards and laboratories of the Hospital for Sick Children, Toronto, under the direction of Alan Brown, M.B.

† Part I, Nature, Etiology and Pathology, *Canad M Ass J*, 1928 **xix**, 46. Part II, Laboratory Findings, *Ibid.*, 555.

result in the development of the clinical and pathological picture of chronic interstitial nephritis. Such a change may occur independent of, or subsequent to, an acute nephritis superimposed on the nephrotic kidney.

No urinary symptoms are complained of during the period before the development of œdema. When much œdema is present, periods of oliguria alternate with those of polyuria. Anuria is frequently an initial symptom in acute cases, and may occur also during the accumulation of œdema in the more chronic conditions. When the patient's weight is more or less stationary the amount of urine excreted is usually about normal. Nocturia is seldom seen.

The intense degree of albuminuria present in nephrosis persists as long as any symptoms are present, and often much longer. This may be for many months, and the consequent depletion of body protein suggests some of the therapeutic measures that may be employed. Generally speaking a decreasing amount of albumen in the urine indicates improvement.

The temperature is often subnormal, with frequent rises from trivial or undiscoverable causes.

The anaemia in acute cases is usually more apparent than real, but in the chronic disease becomes so severe that diet and medicine alone are inadequate treatment. Simple transfusion, which at once cures the anaemia and increases the blood proteins, is indicated.

The hypersusceptibility of these children to secondary infection is but too plainly evident throughout their illness. Such infections are the most frequent cause of death. This proneness to infection applies not only to infections of the upper respiratory tract but to those of operative wounds of any kind, thus necessitating the use of most careful technique at all times.

DIAGNOSIS

Little difficulty in making the diagnosis is encountered in most cases. The presence of œdema and albuminuria associated with the absence of hæmaturia, and the normal blood pressure in cases uncomplicated by cerebral œdema, justify a diagnosis of nephrosis.

The laboratory findings have been described in a previous paper.² Those that are pathognomonic are the hæpæmia, the low blood

protein, and the absence of any increase of the nitrogen end-products of the plasma. Characteristic changes in the urine are the large amounts of protein it contains and the number of casts and white blood cells usually found microscopically.

A differential diagnosis between nephrosis and œdema due to a congenital anomaly of the kidney must sometimes be made in infants. In the latter, urinary symptoms, such as anuria, are usually more severe and persistent, and the blood chemistry test shows evidence of nitrogen retention. In patients of this age, nephrosis must be distinguished from syphilitic nephritis or nephrosis because of the invariably fatal outcome of the latter. In luetic cases, physical examination reveals splenic and hepatic enlargement or other signs of lues, and the hæpæmia is much more marked.

PROGNOSIS

Two important factors in the prognosis have been mentioned, *viz.*, the age of the patient, and the mode of onset of the disease. Practically all children under eighteen months of age recover completely, unless the cases are luetic in origin or a fatal secondary infection occurs. The rate of recovery and its completeness vary directly with the speed with which the symptoms develop. Fifty-five per cent of those of all ages with an acute onset recover, whereas in only about 20 per cent of cases which have developed slowly is there complete recovery.

The practicability of removing focal infections completely is another influential factor in predicting the outcome in any case. It is quite well-known that removal of infected teeth and tonsils has not met with the degree of improvement anticipated in this type of renal lesion, but we now know that this is because in their removal we have only partially eradicated the infective foci. Further search for more obscure foci is indicated.

The absence of complicating infection, particularly tuberculosis, and of other renal lesions, considerably improves the outlook.

As pointed out in a previous paper,² functional tests and chemical blood tests, particularly as to the kidneys' ability to concentrate, and the degree and persistence of the hypercholesterolemia may prove of some prognostic value.

TREATMENT

1 *Rest*—Rest in bed should be enforced in all acute cases and during the acute exacerbations in chronic ones. Little is to be gained by prolonged stay in bed after chronicity has become established. Indeed many chronic cases show definite signs of improvement when allowed up and about.

2 *Focal Infections*—The removal of focal infections in these cases is as important as it is in other types of kidney disease, but the foci are usually more obscure and their removal more difficult than in the more obvious types found in acute glomerular nephritis. Offending teeth and tonsils should first be removed, because, although their removal causes little amelioration of symptoms, a very common source of secondary infection is removed. Thorough search for further infective foci in the accessory sinuses and in the intestine should now be made and proper treatment instituted.

3 *Diet*—The low blood protein, high blood fat, and absence of nitrogen retention in these cases suggested to Epstein^{3, 4} the advisability of using high protein, and low fat and carbohydrate diets in their treatment. Carbohydrates were to be kept low because protein would be better utilized, and because their excessive use causes fluid retention. Such diets as originally described consisted of 120 to 240 gm of protein, unavoidable fats 20 to 40 gm., 150 to 300 gm of carbohydrate and salt to make the diet palatable, with 1200 to 1500 cc of fluid included in the food as a minimum for the patient's comfort. Such diets have met with varying degrees of success in the hands of various observers. Certain modifications must be made in adapting these diets to the use of children, and when these are made they are to be recommended in the treatment of the chronic cases. In acute cases, it is better to use diets such as outlined in a previous paper,⁵ consisting largely of milk, fruits and vegetables with no added salt, and protein adequate for the child's requirements, approximately 50 to 60 gm daily.

The modified Epstein diets advised for use in chronic cases are as follows. In infants, unsweetened protein milk affords the easiest means of providing a relatively high protein, low fat and carbohydrate diet. It may be used even in acute cases of this age. As improvement occurs,

fruit and vegetables suitable to the age of the child, junket, chicken, bacon and, later, cereals are added. In older children 80 to 100 gm of protein, or nearly twice their requirement, are given daily. Carbohydrates are kept low by using large quantities of green vegetables and fruit. The liberal use of these not only furnishes an abundance of whatever protective substances against renal injury they may possess but aids materially in overcoming the secondary anemia present. The salt intake is restricted to that contained in the milk and vegetables given. Fluids are limited to 1,000-1,200 cc daily.

4 *Medication*—Diuretics must be given first place in the consideration of the drug therapy in nephrosis. The persistence of the edema and its gradually increasing resistance to all drugs make its treatment a serious question. Urea is one of the earlier recommended drugs used and is still employed very frequently to advantage in these cases with no nitrogen retention. Doses of 1-2 gm (15-30 grams) may be given thrice daily. It appears to be most beneficial in infants. More recently, the use of acid-producing salts to produce diuresis has become common. Either calcium or ammonium salts may be used. The chloride is the best one to use. Ammonium chloride is more powerful and much less nauseating than calcium chloride, and for these reasons its use is advised. Large doses (1-3 gm), (15-45 grams) must be given two or three times daily. After producing diuresis it should be at least temporarily discontinued. In patients in whom myocardial failure is present, it is best to use digitalis as well.

Another diuretic of an entirely different type is thyroid extract. It probably acts by stimulating the general metabolism which is usually low in these cases. It is worthy of trial in cases resisting other diuretics, as the therapeutic test is about the only one which demonstrates in which cases it will be effectual.

Finally, in chronic cases, where the edema increases despite the proper use of the diuretics mentioned above, one may be forced to use novasurol or merbaphen. This is an organic mercury compound which acts as a powerful diuretic but unfortunately it is a kidney irritant. It should never be used in acute cases of this disease nor in any other type of nephritis. Johnstone and Keith⁶ have recently

demonstrated that the preliminary use of small doses diminishes its toxicity and results in the acquirement of some degree of immunity to its toxic nature when larger doses are given later. The drug must be given intravenously. One-fourth of a cubic centimetre may be given as an initial dose, increased every second day until 1 c.c. is given at the third or fourth injection. Once diuresis starts it should be discontinued. A preliminary course of ammonium chloride for three or four days enhances its action.

Special measures are needed in cerebral oedema, in that the excessive fluid must be withdrawn from the cranial cavity and then diuresis established to prevent its recurrence. Two methods of treatment are practised. In one, a lumbar puncture is done and the cerebrospinal fluid withdrawn very slowly to prevent such an accident as an impacted medulla occurring, ammonium chloride is given by the mouth and saline purgatives by the mouth or bowel. In the second method, 1 per cent magnesium sulphate is given intravenously. Care must be taken that it is given slowly, 1 to 2 c.c. per minute, and that the total amount given does not exceed 10 c.c. per kilo of body weight. The injection is not infrequently followed by a transitory increase in the blood pressure and in the severity of the symptoms. This is succeeded in one-half to one hour by marked improvement in the patient's condition and a fall of blood pressure. Fifty per cent magnesium sulphate, 1 to 2 ounces, is given by the bowel every four hours until catharsis is established. Ammonium chloride is given by mouth. Usually the improvement is permanent, but in some few cases a second injection of magnesium sulphate is needed 12 to 24 hours later. It should not be given sooner than twelve hours after the first.

In cases of anuria, the exhibition of ammonium chloride is not infrequently adequate in starting a flow of urine. Should this measure fail, hypertonic glucose solution (20 per cent)

should be given intravenously. The injection of 300 to 500 c.c. of this solution seldom fails to produce satisfactory results.

5 Operative—In addition to the operations needed to remove focal infections and in the cure of secondary anaemia by transfusion, two others are used in the treatment of this disease. First and most frequently required is that of aspiration of the excessive fluid in the chest or abdomen. There are two indications for the mechanical removal of this fluid. First, the accumulation may be so great as to cause cardiac or respiratory distress of so urgent a nature that rapid relief must be given, and this is best accomplished by paracentesis. Secondly, when marked ascites is present and the oedema not very responsive to drug therapy, aspiration of larger amounts of ascitic fluid on two or three occasions often produces satisfactory results. Great care must be exercised not to introduce secondary infection.

The other operation used is that described by Edebohl of stripping the capsule of the kidney. This should not be done until other measures have failed, as the operative mortality due to secondary infection is high. Two such operations have been done at the Hospital for Sick Children. One resulted in striking benefit to the patient, the other ended in death a few weeks later from secondary infection.

6 Hydrotherapy—Hot packs have been and are still used in treating oedema in these cases. We have found them useless, and were unable to demonstrate, by weighing the patient before and after, that any fluid loss at all occurred. Some patients even gained weight. Local hot packs over the bladder and kidneys are sometimes useful in treating anuria.

The Pathogenesis of Raynaud's Disease—Iwai and Nin conclude that Raynaud's disease is due to the operation of auto-haemoagglutinins and not to a vaso-motor neurosis. The attacks are due to mechanical

occlusion of the vessels in consequence of the agglutination of the blood corpuscles, a condition of things precipitated by exposure to low temperatures.—*Die medizinische Welt*, June 16, 1928

ANTI-TUBERCULOSIS MEASURES IN RURAL DISTRICTS*

BY DAVID A STEWART, B A, M D, LL D,

*Medical Superintendent, Manitoba Sanatorium,**Ninette*

EVEN at a World's Congress we cannot pretend to be internationals but must speak each in his own tongue, each from his own viewpoint, and each largely about his own country or province or locality. We can just bring our own national product, with its peculiar local form or colour or flavour, to this great international fair. In spite of peace-parleys and trans-oceanic flights the shadows of Babel still hang over us.

In any country city-dwellers become world-citizens fairly easily, but rural people are more conservative and national in speech and thought, customs and usages. Even within any one country there can be great differences. In Canada, at any rate, west cannot speak for east, or east for west, on any matter of importance. While modes of thought thus differ, and customs and conditions differ also, principles are of more universal application, and the plans of the smallest village can be at least suggestive, even at the antipodes. And it is well worth noting that the fall in the tuberculosis death rate has been greatest in cities and least in rural areas.

My place of work, and therefore necessarily my text, is Manitoba, the central province of the Dominion of Canada. It has a considerable area of wild unsettled land, and a total population of 600,000, one-third being in a single large city. In typical settled rural areas devoted to farming, the population is about ten to the square mile. The chief occupation is farming, though in the non-agricultural parts of the province mining has begun. Most farmers own their farms. The chief anti-tuberculosis effort centres around the Manitoba Sanatorium, with 280 beds, a voluntary institution, performing provincial functions and having a fair measure of provincial and

municipal support. There is, besides, a hospital of one hundred beds, whose particular "parish" is the City of Winnipeg only, while the sanatorium has an interest in both city and country, especially the country.

The Manitoba Sanatorium was begun with the idea that the treatment of sick people, at an early stage of pulmonary tuberculosis, was its greatest, almost its only, function. But much water has flowed under the bridge since that time. We have learned that a sanatorium, like any other group of good citizens, cannot altogether choose its functions, but must take the situations as they are and perform any function that will be most useful in changing conditions for the better. So tuberculous patients have been taken in and cared for in late as well as early stages, indeed, more late than early, sometimes even moribund, tuberculosis of all organs and all forms, and sometimes non-tuberculous pulmonary conditions as well. Teaching began with patients, spread to doctors and nurses and to the people of the province generally, and has been perhaps most serviceable of all since the students of the provincial medical school began to come, fifteen years ago. They have come ever since, practically all of them.

At the very beginning we saw the importance of better and earlier diagnosis, and saw the duty of the Sanatorium in this part of the big work. Gradually we have gone farther and farther afield, and now are trying to cover our whole province, in diagnosis as well as treatment, and in search as well as diagnosis.

Every tuberculosis sanatorium and hospital should have its own parish, its own field of work, be it city, county, province or state, and all within that area that relates to anti-tuberculosis effort should have a common centre. In rural areas we believe that centre should be the sanatorium. It should not be considered a work of supererogation for a sana-

* Prepared for the full session of discussion upon "Anti-Tuberculosis Measures in Rural Districts," at the International Congress on Tuberculosis at Rome, September, 1928.

torium to do systematic missionary work throughout its territory, but one of its primary and principal duties. Diligent search for people in its own local field may be quite as worthy a work as research in the broader field of tuberculosis in general, and one will be quite as instructive as the other.

In the past three years the particular parish of the Manitoba Sanatorium, the rural areas of a prairie province, has been fairly extensively and intensively cultivated, and we are beginning to learn how very workable and fruitful these methods are, and how well suited to rural areas. Members of the medical staff, with a public health nurse, have gone out in parties of two, three, or four, with a portable x-ray apparatus and a technician, to conduct "clinics" here and there throughout the province. Most of the centres have been small "towns" of two or three hundred to a thousand population. Each clinic draws from one to two hundred people for examination from a circle fifty to eighty miles in diameter. City people demand care at their own doors, in Manitoba as elsewhere, but the more widely country people are scattered, the farther they are willing to travel for this or any other purpose. It is as easy to bring the country suspect forty miles for an examination as the city suspect from the next block.

In good time before a "clinic," all doctors in a considerable area have been communicated with, indeed, all in the province have had notices. Public health nurses of special experience have traced up "contacts" and persuaded them to come. Such a "clinic" continues usually through two days and takes from six to ten "doctor-days," a big "doctor-day" being about twenty-five average examinations. Of real suspects not so many can be examined. X-ray plates, single, or stereoscopic when necessary, are made freely. Indeed, few patients are seen without x-ray plates. It is in these doubtful or borderline cases that plates have their greatest value. A few plates can be developed at the time, but most are carried back to the sanatorium to be developed and read at leisure. Ample notes are taken and as soon as possible after a "clinic" the evidence in each case, including that of the x-ray plates, is summed up, typed and sent back to all doctors concerned, health

officers, health departments, etc. One copy of a report of the one hundred and fifty or more examinations in one such "clinic" runs to about thirty closely written pages.

Without the hearty co-operation of the local doctors such a visit of the sanatorium staff would be a failure, or at the best would do harm as well as good. But we have never in even one case failed to get this co-operation. Why should we, when we bring the best we can in diagnostic facilities and skill and place them freely, *and free*, at the disposal of any patients the doctors care to bring? In such "clinics" and with the sanatorium itself as an all-the-year-round stationary diagnostic centre, we have in fourteen months examined about 3,500—mostly contacts and suspects—about one in a hundred of the rural population of the province.

Now, one in a hundred taken at random is just 1 per cent, a small proportion. But a well chosen one, searched out of a hundred by following clues, a one in a hundred made up altogether of contacts and suspects, a one in a hundred that includes most people the doctors and nurses know of, or that official records of illness and death lead to, such a one in a hundred, may, and indeed does, take in a very considerable proportion of the people who need most to be examined. From 50 to 75 per cent of those so far examined were known to be "contacts."

Many old sanatorium patients and others known to have had tuberculosis are seen, and this is very desirable, especially when the reviews are made by members of the sanatorium staff who already know these patients. But the sensational feature of the summing-up of these journeys is the number of *discoveries* of disease made in them for the first time. In a considerable series of examinations 12 per cent were found to be tuberculous, nearly one-third of these in the active stages. In the same series 11 per cent besides were suspected and considered in need of careful watching. So when the group examined is made up of contacts and suspects and known cases not under institutional treatment, the definitely tuberculous have been found to be one in eight, the actively tuberculous one in twenty-four and, besides these, the definitely suspected of disease, one in nine. These "clinics" evidently gather in fairly well those who need to be seen and known, and treated or kept under observation.

The amount of disease and disability found, apart from tuberculosis, is another sensational finding. Of the people seen only a few consider themselves really ill or are at present under doctors' care. Even those found to be ill have not yet made the decision that they need medical care. Yet, among these fairly ordinary members of the community, besides tuberculosis, 11 per cent had septic infection of the lower respiratory tract, one-fourth of whom had reached already a stage of definite bronchiectasis, 28 per cent had very bad teeth and gums, and 25 per cent septic tonsils, both of which were keeping up filthy mouth conditions, impairing health and even, in most cases, already causing definite symptoms. A few very various disabilities and diseases were found also, in heart and cardio-renal relations, gall bladder, pelvis, intestine, nose and throat. Among others were gonorrhea, arthritis, trachoma, infected sinuses, varicose veins, chorea, dysmenorrhœa, actinomycosis, blood dyscrasias and, as would be expected, asthma, hay fever, malnutrition, rickets, empyœma and many pleurisies.

PRINCIPLES STATED

This brief account of the development of anti-tuberculosis work in the rural areas of a prairie province has already indicated something both of things done and conclusions reached. Some of the main principles of the work as we see them might be put down a little more fully.

A first principle, we consider, in both sanatorium and field work, is that tuberculosis is a family, community, and state problem, as well as an individual problem. When even one man in a province or country is tuberculous, that province or country is to that extent tuberculous. Treatment of the sick man—compassion first—may make the stronger appeal to most people, but treatment of the infected state—safety first—is the more important measure. Cure is good but prevention is better. The history of epidemiology shows that disease has been conquered more by prevention than by cure. But, fortunately, the cure of the tuberculosis of the man and the cure of the tuberculosis of the state can go on well together, indeed, the cure of the sick man is an important part of the cure of the sick state. Still it must never be forgotten that

when even one man within the confines of one state is tuberculous there are the two separate and distinct interests, the interest of the man and the interest of the state, and the interest of the state is paramount.

A second principle, old and familiar, yet, like many other old and familiar principles, such as the Ten Commandments and the Golden Rule, needing to be restated often if it is not to be forgotten, is this, that *every case of tuberculosis comes from some previous case*. Whatever environment may be, and it is a tremendously important matter, there can be no infection and no disease without the actual transference from one individual to another, directly or indirectly, of the germs or seeds of disease. Life comes from life, wheat from wheat, tares from tares, and tuberculosis from tuberculosis. If every single present case, therefore, were fully dealt with by diagnosis, observation, treatment, segregation and adequate control, there would be no future cases. There will be tares among our good grain to-morrow only as we allow tares to grow and ripen and scatter in our fields of grain to-day. There will be tuberculous disease and tuberculosis deaths to-morrow only as we allow tuberculosis infection to slip through our fingers and scatter throughout families and communities and through the whole land to-day. From what we have sown we reap some good grain, but mixed and shrivelled by the tares we have allowed to sow and re-sow themselves in all our fields.

Since each diseased person is a potential scatterer of disease, and usually a daily and hourly scatterer of disease, the big job is to find diseased persons, to make them safe by treatment, or keep them safe by segregation or education, and to search diligently among all who have been in contact with open disease for evidence of infection. It is the big work of the state, or of the volunteers to whom the state sometimes delegates the work and responsibility, to use all the means they can command to make the contacts, the infected and the openly diseased people as safe as possible for themselves, safe for their families, safe for their communities and safe for the country at large, if possible, *absolutely* safe. First, they have to be found, then treated, segregated, supervised and controlled. That needs machinery for case-finding, diagnosis, treatment, segregation. That means the treatment of ac-

tively diseased people as early, as late, and as long as treatment is necessary, the segregation or effective control of spreaders while they are spreaders, and as soon and as long as they are spreaders

This program demands beds, many more beds than most countries or provinces have at the present time, beds in sanatoria, beds in hospitals, beds in places of "preventorium" type, but, always beds, plenty of beds, beds waiting for the people, not people waiting wearily month after month for the beds, beds for treatment, for observation, for segregation, even beds to die in, so that family and friends may not suffer from the last fatal seed scattering from the tuberculosis deathbed. What is the use of finding sick and infective people if we can just wish them well and leave them as we find them? The farmer's indispensable tools are plough and reaper, the carpenter's, axe and saw, the state's indispensable tools in dealing with tuberculosis are a clinic to find cases and a sanatorium or hospital bed to treat and segregate them. With beds enough to take in all who need to come, the very day they are found—the suspected, the active, the not-yet-very-active, the hopeless—the campaign would pass into an entirely new phase. Our worst problems are really the problems of trying to struggle along without beds. The call is for beds, more beds, beds for all needs,—

BEDS

It cannot perhaps be raised to the status of a principle, but can be put down as an observation, that tuberculosis infection is not as a rule passed from person to person of the same generation, but from persons of one generation to persons of another. In an infected circle, suspect the older people as the source, parents and grandparents, uncles and aunts, rather than brothers and sisters and cousins.

It is a truism that early disease does not declare or report itself, or come automatically for treatment, but must be hunted for. Much the same is true of moderately advanced or advanced disease. It also must be hunted for. Most things we want to find must be hunted for, such as gold, silver, precious stones, knowledge, skill. They do not drop themselves down at our doors. Not much of value comes to us without trouble and sweat. Tuberculosis which is left to find itself usually staggers in

hopeless, after spreading the seeds of disease broadcast throughout family and community. If people are to be made safe for themselves and the community, at the right time and in the right way, they must be hunted for.

Our whole plan of dealing with sickness is a poor plan. Modern medical science is wonderful, but the system of applying it to the needs of people is mediæval. Under this system the first diagnostician is always unskilled, and always has a motive for postponing diagnosis, the first diagnostician being the sick or suspected man himself. Before he even says "Good-day" to the man of skill, the physician, the sick man must decide, first, that he is sick and, second, that he is sick beyond the ordinary means of repair, such as rest which he can himself apply, and so needs skilled diagnosis and treatment. The skilled man comes in only after the unskilled man has made these two decisions, and he almost always makes them late.

The ideal solution, of course, would be that all people, rich or poor, in country or city, intelligent or ignorant, sick or well, or half-sick or half-well, should each year, or each half-year, be looked over thoroughly, system by system, function by function, part by part, with the use of x-ray plates, and an appraisal made, and a decision reached as to what repairs are necessary. Such an examination would necessarily be costly, for if not made well it is better not made at all. But this plan belongs to the future. People in general are not ready to ask for such examinations, and medical men, in our country at any rate, are not quite ready to make them. It is about time, however, that such routine examinations, for admission into training schools of hospitals, or into the army, or of an immigrant into a new country, should be made in this thorough-going way, and always with x-ray plates of the chest at least.

In the meantime, while waiting a half-century for the more perfect plan, we must fall back on some such temporary plan for case-hunting as the one already described. And even with this partial plan we will get most of what we are looking for, if we bear in mind that each case of tuberculosis comes from some previous case, if we trace up open disease and death, wherever they have been, and concen-

trate on contacts and suspects and known disease

One principle about such a survey is that it should be both intensive and extensive. If there must be a choice, let it be intensive. Make few examinations thoroughly, with good facilities and skill, rather than twice as many hurriedly, with fewer facilities and less skill. Even with all facilities in office or hospital, the boundary line between the tuberculous and the non-tuberculous is often difficult to define without leaving many under the Scotch verdict "Not proven." Out in the country, away from office and hospital, the difficulty is greater, therefore, such work should be careful and deliberate, and well-made, well-read x-ray plates are a necessity.

We consider it quite the best plan, almost an essential part of the plan, that this work should be done by members of the sanatorium staff. As has been stated, each sanatorium has, or should have, its own parish, its own field to cultivate, and in this field should search, diagnose, treat, teach and supervise. Sanatorium men need to see where tuberculosis grows, and how it grows, that is, they need field work, and cannot keep proper breadth of view without it, and on field work all the time men grow stale, lose the infective enthusiasm such pioneer work needs, and are better to come back for a time to the variety and orderliness and facilities of sanatorium duty. The outside clinic, an occasional part of the sanatorium staff man's duty, say, one week or month out and two or three or more weeks or months in, might be a good arrangement.

Finding people who need treatment, bringing them in for treatment, following them after treatment, getting in touch with their families and their doctors, and keeping in touch, is much more likely to be done well by one organization than by several. No sanatorium is doing its duty by its parish, or by itself, which has not a clinic with a wide-open door, and if the clinic be just extended and multiplied to cover the whole of the sanatorium parish, be it county, or province, or state, or country, the benefit all round is much greater. Experienced medical men, with the standing of sanatorium staff positions, if they have the skill they should have and any personality at all, should be welcomed by any doctor in any community.

A necessary part of the plan, which makes for good feeling between sanatorium and physician, is that every bit of work done, every examination, every note, every x-ray plate reading, every recommendation, shall be communicated to the doctor of the person examined. In small communities, where people go from doctor to doctor, the easiest plan is to send a full report of all cases to each doctor. Reports are sent also to public health departments, municipal health officers, etc.

While the examination is primarily of contacts and suspects, and to rule out or rule in tuberculosis, still, once the man has come in, the examination should be as full as possible, and deal not only with tuberculosis but with general health. Bad teeth, septic tonsils, bad posture, malnutrition, should be enquired into and brought to the attention of the regular physician. The physician, it must be remembered, sees in the community only those who consider themselves sick, and sick enough to need his services, and few of the people we class as contacts consider themselves in these categories.

Another principle of importance is that anti-tuberculosis work should impose as little financial burden as possible on the ordinary individual. Treatment may usually need to be paid for in whole or in part by the sick man or his family, but in dealing with a long-drawn-out disease like tuberculosis payment is almost always a hardship, or in time becomes a hardship, almost always tends to postpone or limit the time of treatment, and often prevents treatment altogether. The burden of treatment of the indigent should be carried by the community in some form, and there is no reason why ordinary good citizens should not be at least part carried in the same way. A plan along this line in Manitoba, the treatment of the poorer people wholly carried, and of the ordinary people part carried, by a general municipal levy, has brought into the sanatorium three or four or five times as many as ever came before, for their good and the good of their families, their communities and the province at large as well.

After all, when a man with far-advanced, hopeless disease is found and sent to a hospital, who is it that benefits? The man often would prefer to go on as he had done before. Segregation to him may mean almost unwilling imprisonment, though safety for the community

All diagnosis, treatment, segregation and observation of a tuberculous person is diagnosis, treatment, segregation and observation of a tuberculous community or state. Almost everything we do is partly for the man's good and partly for the state's safety. In so far, then, as the man is treated to make the state safe, the state should help with the burden of payment. The state of the future, perhaps as municipalities, may carry the whole burden, and the tendency is very definitely in that direction in the western Canadian provinces.

The state, whether by municipalities or provinces or countries, cannot do everything the people need, out of ordinary revenues. Indeed, the state has already become a sort of community cow, that everybody wants to milk and nobody wants to feed. But the science of spreading over the community the burdens of things we need has not advanced so very much since the days when Matthew the publican sat at the receipt of custom. The state, it is true, cannot pay for all needed things, but it should do what is better, that is, plan for all. We need money much, but we need plans more.

Treatment should be free for those who cannot pay, but there is little doubt that diagnosis, at any rate, in occasional distinct clinics by a sanatorium staff, should be free for all. This is essentially missionary work, that is, work done by those who see a need for those who have a need but do not see it. The big thing is to have the people who need to be dealt with, *dealt with*. If everything done to eradicate tuberculosis were to be charged back upon the individuals who benefit, all anti-tuberculosis effort would

stop this very day. Meantime, many good services have to be more or less the voluntary services of forward-looking citizens. The case finding of the Manitoba Sanatorium has been so far a voluntary service, the only special fund for which has come from the sale of Christmas seals.

Such "case-finding clinics" find late, unreported cases. They find early cases among the contacts and suspects. They find many disease conditions, major or minor, other than tuberculosis. They keep up some supervision of those who have never been hospitalized and of others before and after hospitalization. All these things are of great importance. But perhaps they do most in what they teach. For, after all, *things done* teach more and better than *things said*. These clinics, by what they do, even if nothing is said, teach the community that tuberculosis spreads like noxious weeds, that each case comes from some previous case, that as ripe weeds are sure to have circles of seedlings around them so neglected tuberculosis cases are surrounded by infected "contacts," that the apparently well must sometimes be suspected, that the routine examination of the well is a good principle, and that tuberculosis contacts are in a special class and should be watched. They teach also that tuberculosis is not a stroke of fate but the effect of causes, that in part at least it can be controlled, and even banished, by man.

The best anti-tuberculosis measures we have discovered for rural districts are sanatorium beds, sanatorium clinics, stationary and traveling, and sanatorium teaching.

Clinical Experience With Irradiated Ergosterol—It is the opinion of Alfred F. Hess and J. M. Lewis that irradiated ergosterol is by far the most potent of the antirachitic agents. It is an absolute specific. Cod liver oil in the amount of which it can be given is a specific of limited dependability—only moderately effective for the average infant, uncertain in action for the rapidly growing infant, and ineffective for the premature. Irradiated ergosterol is quite as valuable in tetany as in rickets, and in both disorders is remarkable for the rapidity as well as for the reliability of its action. As yet, however, no sufficient clinical experience has been had to define its proper dosage. Furthermore, the various preparations cannot be evaluated, as they have not yet been assayed on the basis of the number of

"curative units (rat)" which they contain. The amounts now recommended and employed are unnecessarily high, as shown by the fact that they induce an excess of calcium and inorganic phosphorus in the blood in the normal as well as in the rachitic infant—hypermineralization. Too great emphasis has been laid in rapidity of action. It would seem advisable, before distributing unreservedly to the medical profession this potent concentrate, to make a more thorough clinical study of its dosage, as has been done in regard to other potent extracts. In view of its reliability, its high degree of activity and its ease of administration, irradiated ergosterol should prove a most valuable addition to the rapidly increasing fund of specific antirachitic agents—*J Am M Ass*, 1928, xci, 783.

INGUINAL HERNIA AND ITS RELATION TO COMPENSATION

By W W RUDDICK, M D

Montreal

THE term "traumatic hernia" has been used rather loosely to designate, (a) cases which appear during or following some effort, (b) those due to direct violence, and (c) those due to some disorder of the muscular mechanism of the groin. The term should be applied to cases in which the hernia appears immediately after violence severe enough to cause a severing of the overlying muscles and protective fascia, if not of the skin.

The majority of herniæ have been designated as "effort" herniæ, which means that they are not the result of one effort alone, but the cumulative effect of repeated efforts, such as lifting, coughing, sneezing, straining at stool, with at some time, perhaps, unknown to the individual, a sudden effort (that in a normal man would be harmless) which converts a partial or incipient or potential hernia into an actual one.

A true "traumatic" hernia should call for compensation if the individual be engaged in work as an employee at the time of injury. On the other hand "effort" hernias are the cause of much trouble in deciding if compensation under the same circumstances should be allowed.

Mock¹, in his article "Compensable Hernia," points out that the English courts prior to the compensation days made the decision that traumatic hernia could occur only from a direct violence resulting in a definite tearing or rupture of the abdominal wall. All other herniæ were considered to be due to congenital defects, and were similar to all other diseases which might occur coincidental with occupation, but not related to it. The decision of the English courts at that time was no doubt arrived at chiefly on their understanding of the etiology of hernia. This entailed an understanding of the anatomy and embryology of the inguinal region. It is my purpose here to review these, so that we may see things perhaps in the same light as did the English courts.

ANATOMY

The inguinal region is the lateral region of the lower zone of the abdomen. Through it runs the inguinal canal which contains the spermatic cord and the ilio-inguinal nerve in the male, and

the round ligament of the uterus and the ilio-inguinal nerve in the female. It is an oblique canal about four cm long, slanting downwards and medialwards and placed parallel with and a little above the inguinal (Poupart's) ligament. It extends from the abdominal inguinal ring (internal abdominal ring) to the subcutaneous inguinal ring (external abdominal ring). It is bounded posteriorly by the transversalis fascia, extraperitoneal connective tissue, peritoneum, conjoined tendon, and reflected inguinal (Poupart's) ligament, above, by the arched fibres of the obliquus internus and transversus abdominis, below, by the union of the transversalis fascia with the inguinal ligament and at its medial end by the lacunar ligament, in front by the integument, superficial fascia and aponeurosis of the obliquus externus throughout its whole length, and by the obliquus internus in its lateral one-third. The space between the inferior margin of the transversus abdominis and the inguinal ligament is protected by the transversalis fascia, reinforced throughout most of its anterior surface by the conjoined tendon and interfoveolar ligament.

The conjoined tendon of the obliquus internus and transversus is formed mainly by the lower part of the tendon of the transversus and is inserted into the crest of the os pubis and pecten pubis, (ilio-pectineal line), immediately behind the subcutaneous inguinal ring, thus serving to protect what would otherwise be a weak part in the abdominal wall.

The interfoveolar ligament (of Hesselbach) is lateral to the conjoined tendon. It is a ligamentous band, sometimes containing a few muscular fibres, extending from the inferior border of the transversus muscle to blend inferiorly with the inguinal ligament. When well developed, the edge of the conjoined tendon and interfoveolar ligament blend so that no medial inguinal fossa exists. Thus, with a well developed transversalis fascia, which is usually a strong fibro-aponeurotic layer, is sufficient to retain the viscera within the abdomen. The spermatic cord in the male and the round ligament of the uterus in the female pass through the transversalis fascia at a spot called the abdominal inguinal

ring, (this opening is not visible externally since the transversalis fascia is prolonged on to these structures as the infundibuliform fascia) Passing along the inguinal canal they pass out through an interval in the aponeurosis of the obliquus externus, just above and lateral to the crest of the os pubis. This interval is known as the subcutaneous inguinal ring.

Sir Arthur Keith² considers that there are two guards to man's inguinal canal, an inner and an outer. The outer guard consists of that part of the external oblique which arises from the 8th, 9th, and 10th ribs, and ends over the flank on each side of the external ring. With every effort we make, this muscular guard is set reflexly into action and strengthens the outer wall of the inguinal canal. The inner guard consists of the inguinal ligament, conjoined muscle, and that part of the internal oblique and transversalis which, rising from the outer part of Poupart's ligament, passes above the internal ring, to end in the conjoined tendon. When the conjoined muscle contracts it acts as a shutter rather than a sphincter. The lower edge becomes closely approximated to the inguinal ligament, thus closing the inguinal gap. This conjoined muscle frequently has a high origin from Poupart's ligament, is poorly developed, and, instead of consisting of heavy muscular fibres, is replaced by a thinned-out aponeurotic layer, with a short muscular belly, thus leaving a portion of the transversalis fascia with little or no support. It is in these cases that direct herniæ are found.

Inspection of the peritoneal aspect of the inguinal region, when viewed from behind, will show the peritoneum raised in five folds by more or less prominent bands which converge to the umbilicus. The middle umbilical ligament, situated in the middle line, is covered by a fold of peritoneum known as the middle umbilical fold. On either side of this a fold of peritoneum round the obliterated umbilical (hypogastric) artery forms the lateral umbilical fold. To either side of these cords is the inferior epigastric artery covered by the epigastric fold. Between these raised folds are depressions constituting the so-called foveæ. The most medial of these foveæ, situated between the middle and lateral umbilical folds, is known as the supravesical fovea. The intermediary fovea is on the medial side of the epigastric fold and is termed the medial inguinal fovea. The third fovea is lateral to the epigastric fold and is termed the lateral inguinal fovea. The lateral fovea is naturally the

deepest of the three. From each fovea a process of peritoneum may be developed, if from the medial inguinal or supravesical foveæ, a hernia of the direct type descends, if from the lateral inguinal foveæ, whose floor corresponds to the abdominal inguinal ring, a hernia of the oblique type descends. Often the obliterated hypogastric artery is represented by a fibrous cord and is seen coursing over the dome of a direct sac, causing the sac to bulge forward on either side of it. Oblique and direct herniæ very often coexist in the same patient, and on the same side. Nearly all large direct herniæ are accompanied by an indirect sac, being separated by the epigastric fold. These are by some called "saddle herniæ," and often the epigastric fold is almost indistinguishable, making it difficult to state whether the hernia started as a direct or an indirect hernia.

EMBRYOLOGY

In the early human fetus, long before the descent of the testicle has begun, there is found a strand or cord of tissue issuing from the substance of the groin and passing to the scrotum or labium majus. Cleland termed this inguinal strand the gubernacular cord. At the end of the fourth month of fetal life we find a plica of peritoneum running from the epididymis and testis down to the future site of the internal abdominal ring. Within the plica are included bundles of fetal non-striated muscular tissue. In the fifth month this muscular tissue undergoes a peculiar cellular hypertrophy forming the gubernaculum. The gubernaculum assumes a bulbous form, its thickened end being at its testicular extremity. In the latter part of the fifth and throughout the sixth month of fetal life, the peritoneum, and particularly the sub-peritoneal tissue, takes on a peculiar form of growth, evaginating the adjacent abdominal wall, and apparently pushing its way towards the groin. By the seventh month the gubernacular bud and its hood of peritoneum have made their way into the abdominal wall, the testis following. The gubernaculum retains the same length during the act of transit through the belly wall, this part of the process occupying the seventh month. Behind the testis a process of growth is at work, elongating the vas, the vessels and the peritoneum. By the eighth month the gubernaculum bud has traversed the abdominal wall, and by the ninth it and its hood of peritoneum have established themselves in the scrotum. The neck of the peritoneal di-

verticulum lying within the freshly formed inguinal canal is new. It has been specially formed during the period of descent, only the fundus of the diverticulum, the tunica vaginalis, is old. The peritoneal canal becomes obliterated. Sir Arthur Keith states that even in the third month after birth there are still thirty to forty children in every hundred, in whom the upper part of the canal is imperfectly closed.

Hamilton Russel³ believes that the presence of an abnormal developmental pocket of peritoneum is all that is required to produce a hernia, that practically all herniæ are congenital, that acquired hernia does not exist. In conclusion he states —

(1) Inguinal hernia in young subjects is caused by the presence of a congenital sac and there is no other cause.

(2) Acquired hernia in the young has no existence in fact.

(3) All cases of oblique hernia, occurring at any time of life, are in subjects who are the possessors of a congenital sac.

(4) Subjects who have never possessed a sac, or who have had the sac effectively removed, can never become the subjects of oblique hernia.

(5) I am unable to find any evidence of any kind in favour of the belief that oblique hernia ever occurs at any age independently of the presence of a congenital sac.

Sir Arthur Keith opposes this view and points out that the processus vaginalis remains open in nearly all animals—man and the gorilla being exceptional in having it closed—and in them congenital inguinal hernias are almost unknown. The presence of a developmental pocket of peritoneum cannot be the only factor involved, and is not essential. He holds that without such a pocket a hernia can be produced by the gut forcing its way into the inguinal canal through the shutter-like arrangement which acts as a guard to the inguinal canal. Any strain put upon the muscles forming this guard will cause them to contract reflexly, closing the opening and preventing the protrusion of the gut. Any failure of this contraction will lay the groin open to a hernia. He states that most of the herniæ of infancy take place into the funicular process, a sac of developmental origin, but that, after childhood, the sac and hernia are formed together and simultaneously. Given a weak point in the abdominal wall, there can be no doubt that the intermittent and repeated forces which are generated within the abdomen of every man and child are sufficient to protrude that weak but living and plastic area in the form of a hernial sac.

LEGAL VIEWS ON HERNIA

Evidence such as this would make one feel that the English courts were right in their decision, and because of such a decision at that time, few claims for traumatic hernia were made. Since then things have changed, and at present practically every case of hernia occurring while an employee is at work is the basis of a claim for compensation. This condition was brought about by broad-minded employers recognizing a certain moral obligation and realizing that any improvement in the condition of the employee rendered him more useful. They were little concerned whether there was such a thing as "traumatic hernia" for which they could be held legally responsible. If an accident occurred, even though these employers were not legally responsible, they felt that a moral responsibility was attached, and compensation and free surgical care were given. If they employed a man with a hernia they knew the industry was not responsible for it. If it grew gradually worse without any cause, again they were not responsible. But if, as a result of an accident or severe strain, the hernia became strangulated, at once doubt as to responsibility entered the case, and the decision was rendered in favour of the employee. If they hired a man who showed no sign of rupture at the employment examination, but later suffered an accident or severe occupational strain, and as a result hernia appeared, compensation and free surgical care were given because in the man's mind the accident caused the trouble. Such, says Mock, was the attitude of several concerns at the time of the passage of the Employee's Compensation Act. In fact these very laws were an expression of the new humane influence which had entered industry. The administration of these Acts was placed in the hands of industrial commissioners whose members were laymen rather than lawyers. Influenced by the generous attitude of certain industries, and guided by sentiment and a consideration of moral rights, combined with their meagre legal knowledge, the decision of these various commissions were often at variance with those rendered by the courts in the past. Thus, employees began to seek compensation for many conditions which heretofore had not been considered compensable, and included among them were herniæ which developed during employment.

Had the industrial world been of the same attitude as mentioned by Mock at the time of the passing of the first Compensation Act, no diffi-

culty would have been met in dealing with herniæ which became apparent while the employee was at work, but all were not of the same opinion, and for this reason many cases are left to the Courts, aided by orthodox and unorthodox medical evidence, to place the responsibility.

Under the present system in our courts, where the medical evidence, as heard by a judge and jury is always contradictory, and where one medical man's evidence bears as much weight as another, no matter whether he be a surgeon of vast experience, or a general practitioner with no surgical experience, great injustice may be done either employee or employer. In this respect it is felt that if the courts were to use the testimony of experts of the court's selection, and not of the selection of the claimant or defendant, greater justice would be rendered all concerned.

The term "traumatic hernia" should be confined to those cases which are the result of violence and show definite signs, or give definite symptoms, within the first twenty-four hours after injury. The others, which are included under the general name of traumatic hernia, are called by the German writers "accidental hernia." Patterson gives the following signs and symptoms as indicative of a traumatic hernia.

(1) Immediate descent of the hernia following the alleged injury or strain.

(2) Severe pain in the region at the time and following the injury, severe enough to require medical aid within the first twenty-four hours.

(3) Severe prostration, causing the employee to cease work immediately.

(4) Symptoms of such severity that they were noticed by the claimant and communicated to the employer within twenty-four hours after the occurrence.

(5) The trauma or strain must be adequate.

He felt that if two or more of the criteria are lacking, a case cannot be justly maintained to be of traumatic origin.

Mock advocates that the term "compensable hernia" be adopted to include all cases of true traumatic hernia, and all cases of accidental hernia, in which the force causing their development is directly the result of some unnatural occupational hazard. In favour of the hernia being due to "unnatural causes" we have the following—

(1) Definite proof that the hernia did not exist previously. As the burden of proof of a pre-existing hernia rests with the employer, a

physical examination of all applicants for positions in industry, no matter in what capacity, should be made.

(2) A definite history of an accident, or if hernia occurred coincidentally with strain or a severe effort far in excess of that which the man's muscular developmental stature or past experience in the occupation should call for. Such factors would compose the unnatural occupational hazards, as opposed to the natural strain of his ordinary work.

(3) The appearance of a hernia immediately or very shortly after the occurrence of one of these unnatural exciting causes.

(4) The examination of the hernia revealing that it is of small size, seldom as large as an egg, and usually within the canal or just appearing at the external opening.

(5) At operation the peritoneal sac is small, thin, and seldom protrudes throughout the entire length of the canal. Adhesions of the mesentery or viscera to the sac are never present.

In favour of the hernia being due to natural causes are the following.

(1) History or knowledge of a hernia already existing.

(2) History of hernia in childhood, which was apparently cured by a truss and has not been present for several years.

(3) Presence of hernia at some other abdominal orifice, showing a tendency towards this condition.

(4) Weakness of the structures forming the walls of the inguinal canal.

(5) A family history of hernia is a strong etiological factor in favour of the employee being congenitally predisposed to the condition.

(6) The age of the patient is an important factor in determining the natural or unnatural cause of the hernia.

(7) Other etiological factors, such as recent debilitating diseases.

(8) Certain conditions found during examination of the hernia which indicate that it was due to natural causes. For example a large hernia indicates its pre-existence, a discoloration or deep depression of the skin over the hernia indicates that a truss has been worn, and that therefore a hernia must have existed.

(9) The condition found at the time of operation will often indicate that the hernia was of long standing and therefore not due to the alleged injury, for instance, a thickened well formed sac,

adherent mesentery or intestine within the sac, and heavy fibrous bands in the hernial sac

From this it would seem that true "traumatic" hernia occurs rarely if at all and that the majority of hernie that come before our courts or commissions for decision are really "effort" hernie. All of these then, or almost all of them are of gradual production. Repetition day by day of straining at stool, stooping, lifting, coughing, and all other bodily movements force the semi-fluid abdominal contents against their containing walls, and gradually cause evagination of the weakest points of the abdominal wall, then the sudden effort, which in a normal man would be harmless, turns a partial or potential hernia into a larger one.

If the courts or commissions are to disregard gradual production and decide that this last

effort, great or small, is the cause of the man's hernia, and compensation be given, then all employees with partial or potential hernias are financial risks to their employers, a risk which would not be taken should the employer know of it, also those persons with an established hernia would not be eligible for any kind of employment, because of the fact that the gradual production as mentioned is going on and increases the size of the hernia, and at any time he could make a claim for aggravation.

It would therefore seem that the English courts were right in their decision made prior to the days of compensation.

A CONSERVATIVE METHOD OF THE CONTROL OF UTERINE HÆMORRHAGE BY X-RAY

By A. STANLEY KIRKLAND, M.D.,

Saint John, N. B.

UTERINE hæmorrhage is always an alarming condition whenever it is encountered and should be an indication for an immediate investigation as to its cause. Such bleeding may be caused by a great variety of conditions, but this discussion is limited to a type of case which shows very little if any gross evidence of disease. These limitations have been imposed because in the selection of cases for treatment by x-ray it is obviously unwise to include any case where the indications are clear-cut for surgical measures, such as the presence of large multiple fibroids, and again it is unwise to invade a field better served by radium, which field includes carcinoma of the cervix.

The group of cases here reported includes women from fourteen to fifty-nine years married and single, all presented as their chief symptom menorrhagia and many also metrorrhagia. The majority showed no evidence of gross abnormality on pelvic examination. A few cases which will be noted had small fibroids. Many cases with other complications have been treated by us with varying degrees of success. Some spectacular results have

been achieved, some have been most discouraging. Many such complicated cases have therefore been eliminated from this series, so as to present a description of a patient with a clinical entity which, when recognized, may with safety and assurance be referred to the radiologist for treatment.

The women treated not only were bleeding, but were bleeding severely. All of them had had some previous treatment, varying from rest in bed to repeated curettage, some were dangerously anæmic, and one woman was practically exsanguinated, to such a degree that a blood transfusion did not improve her to a point where she would be acceptable as a surgical risk.

At the beginning of the series five years ago, the cases came to us either because they refused a suggested hysterectomy, or because the general condition was not sufficiently good to allow a good prognosis following the shock of a major pelvic operation. In the last few years, our clinical group has recognized suitable cases and more promptly referred them to us.

The members of this group may be arbitrarily divided into three classes (1) the very young

girl who has but lately established her menstrual cycle and who develops an alarming menorrhagia, (2) the woman of childbearing age, whether parous or not, who complains of excessive bleeding at or between her periods, often accompanied by dysmenorrhœa, (3) the older woman at or near the menopause, whose profuse bleeding is alarming to such a degree that an artificial menopause, quickly produced, is considered advisable

The treatment in each class is bound to vary according to circumstances and perhaps this may be best shown by quoting illustrative case reports

CLASS 1

A girl of 14 referred with a history of severe bleeding at each period for a year, in fact from the date of first menstruation. She was pale (hæmoglobin 30 per cent), confined to bed, appetite poor, sleeping poorly. It was necessary here to do two things: (1) To arrest as soon as possible the bleeding which had made an invalid of this child, and (2) to preserve her menstrual function. Therefore, she was given an x-ray treatment over the pelvis anteriorly with the following factors: 5 milliamperes, 200 peak kilovolts, 50 centimetres distance, one millimetre of copper plus one millimetre aluminium filter, ten minutes exposure. The following day the same dose was administered over the posterior pelvis. This was repeated in four weeks. In the meantime she continued in bed. At the end of three months this child was up and about. Her hæmoglobin was 70 per cent and her menstrual flow was normal in amount with a three day flow.

CLASS 2

(a) A young married woman, of 29, with menorrhagia and metrorrhagia, two healthy children, has had an unsuccessful curettage. There was no gross disease in the pelvis, no obstetrical tears. She was unable to walk, bleeding continually. Hæmoglobin was 25 per cent. She was so ill that she expressed indifference as to the possibility of future pregnancies. She was given an anterior and posterior pair of exposures as above, except that the time was doubled, another pair at the end of four weeks, and a final treatment at the end of eight weeks. Her bleeding ceased at the end of eight weeks and she was amenstrual for six months. After that her menstrual cycle became normal. Her hæmoglobin reached 85 per cent and she gained thirty-five pounds in four months. There have been no pregnancies since the treatment.

(b) A married woman of 37, with pulmonary tuberculosis and severe uterine bleeding, and with such severe anæmia that she already showed cord symptoms. She was given four pairs of treatments at intervals of four weeks. Her bleeding ceased at the end of the fourth month, and she has not menstruated since. Subsequently, her general condition has very much improved and the chest condition is quiescent.

CLASS 3

(a) A spinster of 41, with menorrhagia and metrorrhagia for three years, bleeding for last twelve weeks steadily. Curettage six months ago with no relief. A pelvic examination was negative. It was decided to precipitate the menopause. Three pairs of treatments were given at intervals of four weeks with

complete cessation of flow and a gain of twenty pounds, and with none of the discomfort of an ordinary change of life.

(b) A married woman of 43 with no children, menorrhagia for five years off and on. Lately she has bled steadily. She was very irritable, anæmic, bedridden, a very difficult invalid. Pelvic examination showed a small fibroid but nothing else of note. To bring on an artificial menopause it was necessary to give her four pairs of treatments at intervals of four weeks. She still has regular menstruations of one day duration, some hot flushes, and occasional headaches, but she is doing her own housework and has gained weight.

Thirty-eight case reports are here reviewed. The reports quoted have been completed for at least two years. There have been no failures, in spite of the fact that three women did not receive the full prescribed dosage. These three were so much improved that they refused the final treatments. They were public patients and it is a noteworthy fact that free patients are more difficult to control than paying clients. Not all, but a majority, of the women suffered slight ionizing sickness, which in no case was severe. It is desirable that these patients should spend the first month in bed and have as much rest as possible until the bleeding is controlled. There is no necessity for medication other than to give good food, provide plenty of sleep and fresh air and perhaps a tonic of iron.

The production of artificial menopause by x-ray is safe, rapid and satisfactory to the patient, because in most cases the unpleasant features of the menopause are cut short, if not obviated. X-ray control of uterine hæmorrhage in women of the childbearing age must be advised and prescribed carefully with reference to the possibility and desirability of future pregnancies, but in all our cases this was secondary to the necessity of preserving the life of the patient. Nevertheless, by judicious estimation of dosage, menstruation was preserved. This result has a decidedly good psychological effect if nothing else. It is in the treatment of the menorrhagia of very young girls that the radiologist finds his greatest problem, for such children have a long expectation of life and any interference with their menstrual functions may entirely discolour their outlook on life. Therefore, dosage must be cut down to the minimum and treatment stopped at the earliest sign of arrest. In our cases to date, only one pregnancy has been reported following x-ray therapy of the pelvic organs, and this was interrupted at five months due to extensive kidney damage.

POST-OPERATIVE VOMITING ITS CONTROL BY INTERSTITIAL INJECTIONS*

By M A R YOUNG, M.D., C.M.,

*Lamont Public Hospital,**Lamont, Alta*

POST-OPERATIVE vomiting, dreaded by the patient and often a worry to the surgeon, is a condition which is not considered seriously enough by many men who do operative work. Treatment directed toward the control of vomiting ought to be as much a part of the total surgical routine as the giving of morphine to relieve pain. This does not appear to be the case.

Dolan¹ discusses the value of glucose, given intravenously, using insulin in sufficient amounts, as a treatment for severe and often uncontrollable post-operative vomiting. The thought comes to one, since this treatment works in pernicious vomiting, why not institute it earlier before the vomiting becomes severe, or even before it has started at all? Intravenous therapy of this kind requires the determination of the blood sugar, the CO₂ tension, etc., and the procedure becomes rather too technical for the average man to engage in.

For a number of years it has been a routine practice with us to give every patient who has undergone a major operation an interstitial injection of saline, Ringer's formula, or a combination of Ringer's saline with a 5 per cent solution of dextrose in equal proportions. The value of this therapy was impressed upon us by its application in Crile's clinic at Cleveland. We also make use of Bartlett's method of adding novocaine solution to the interstitial saline in order to make the administration painless.

The routine giving of 1,000 to 1,500 c.c. of one of the above solutions after each major operation appears to be a method of satisfactorily disposing of the problem of post-operative vomiting. At least, we do not appear to have a more efficient one at the present time. Furthermore, when the patient gets the solutions early, before marked blood changes have taken place, it does not require that

technical knowledge which is necessary for making intravenous therapy safe.

Briefly, the technique of the post-operative interstitial therapy as practised in the Lamont Public Hospital is as follows. As soon as the patient has returned to his bed he is given into the lateral aspects of the thighs 1,000 to 1,500 c.c. of solution, to which has been added 30 c.c. of a 1 per cent solution of novocaine per litre of fluid given. If the needles are inserted so that the solution will run the amount is taken in an hour or less, and is painless then and afterwards. Chemically pure dextrose is used, and the Ringer's tablets are made up for us by Parke, Davis and Company, in such a size that one tablet with sufficient distilled water to make 100 c.c. gives an isotonic solution. The above is a well established treatment in many places over this continent, but it is not used so often as it should be in hospitals where surgical work is done. This technique is more fully described in an article on "Mortality in appendicitis", published in this *Journal*.²

Regarding any treatment which one would wish were universal, three questions are bound to arise. What is its value, what is the risk, and is it difficult to administer?

As to its value, interstitial therapy greatly diminishes post-operative vomiting, lessens nausea to a similar degree, relieves the patient of the intense craving for water, reduces the incidence of post-operative distension, and almost does away with the need of catheterization. In addition, it supplies the drained tissues with fluid, and makes up for that which has been lost during the operation.

A small series of non-operative patients and a similar series of operative patients were given the same amount of fluid from seven o'clock in the morning to seven o'clock in the evening, the former by mouth, the latter by interstitial injection and by mouth if they wished. It is interesting to note that the operative cases

* Read before the Alberta Medical Association, Edmonton, September, 1928.

retained from 200 to 500 cc more of the fluid during this twelve hours than did the non-operative. Might it be suggested that these patients need this amount of water, and if they do not get it by interstitial injection there is no other certain way of giving it whereby one is sure that it will be retained except by the intravenous route?

Lahey³ and Crile and Higgins⁴ stress the need of fluid in the operative patient. The giving of fluids by means of the Murphy drip, though excellent in many cases, very often fails in that case in which it should function, and the very sick patient expels his drip, thereby receiving no benefit. It is in this type of case that the interstitial form of administration demonstrates its usefulness.

There appears to be no risk if ordinary care is observed and asepsis employed. It is hardly necessary to add that the solutions ought to be of the proper strength, temperature, etc. In 1,200 cases in our hospital in which this procedure was adopted we have had three local infections, each one following the addition of a new interne to the staff, suggesting a slip in

technique. There have been no other complications. Considering the immense amount of relief afforded to the patient even the above unfortunate occurrences hardly constitute a risk.

The giving of the interstitial injection, as every one knows, is a simple procedure. A nurse may give it, but we prefer a doctor to take the responsibility. The use of the novocaine makes it possible to give an interstitial injection at any time without any discomfort to the patient and it is often used apart from operations when a patient needs fluids urgently.

In view of our experience with this number of cases, the pleasing results, and the relief to each patient, we would recommend the adoption of this interstitial therapy for all major operations, as a measure adopted in the best interests of that uncomfortable individual, the post-operative patient.

AN UNUSUAL CASE OF DIABETES AND GOUT*

By I. M. RABINOWITCH, M.D.

Montreal

THIS case of gout and diabetes is reported because of (a) the debatable causal relationship between gout and diabetes, (b) the anomalous influence of the insulin administered upon the course of the gout, and (c) the results of synthalin treatment.

A male, (Hospital No. 1128-27), aged 50 years, was admitted to the Montreal General Hospital, March 2nd, with a history of "thirst, dry mouth, frequent urination and weakness."

He was born in Montreal, had measles and diphtheria in childhood, pneumonia in 1915 and typhoid fever in 1917. He stated that for the last ten years he had been suffering from gout, and during that period had been confined to bed at least five or six times a year. The duration of these attacks varied between two and ten days. At each attack potassium iodine and

colchicum or atophan treatment resulted in relief. He had been accustomed to drinking about two or three pints of stout each day.

There was no family history of diabetes. His father also suffered from gout and died at the age of sixty-nine from "anæmia," and one brother, who is alive and otherwise well, has frequent attacks of gout.

The history dated back to February 15, 1927. At that time he was free from any attacks of gout for about one year and, for the first time, noticed excessive thirst, and his mouth "became very dry." Accompanying this thirst there was increased frequency of urination. He stated, however, that, though his appetite was always good, he believed it had increased a few weeks prior to the onset of the thirst. He also said that for three months prior to February he did not feel as strong as usual.

That the diabetes dated farther back than the

*From the Department of Metabolism, The Montreal General Hospital, Montreal.

above history indicates is suggested from the laboratory findings of February, 1926. At that time he received hospital treatment for an attack of gout, and the laboratory records show a fasting blood sugar of 0.13 per cent. The urine contained no sugar. There is nothing in the records to suggest that the mild hyperglycæmia might have been due to defective kidney excretion. The urine contained no albumen, the blood urea nitrogen was 18.5 mgm per 100 c.c., and the creatinine was 1.4 mgm per 100 c.c. At that date there were no other clinical conditions to account for the hyperglycæmia. On February 28, 1927 he consulted Dr. D. Grant Campbell, who during his routine examination discovered sugar and acetone in the urine and advised hospital treatment.

Briefly, the findings of the physical examination on admission, were as follows. There was slight emaciation and an acetone odour to the breath. The lungs were negative. There was a slight degree of hypertension (140/82), and cardiac hypertrophy. The transverse dullness of the heart extended from a point 1 cm. to the right of the mid-sternal line to 10.5 cm. to the left of the same, at the level of the third rib. Both patellar reflexes were absent, the other reflexes were normal.

Both hands showed enlarged interphalangeal joints and the great toe of the left foot was markedly enlarged. There was also some deformity of all of the metatarso-phalangeal joints of the same foot.

The following were the results of the routine laboratory tests —

The urine was clear and pale, specific gravity, 1.036, reaction acid, sugar, plus, acetone and diacetic acid, plus, albumen, a trace, a few hyaline casts were present. The blood red cell count, 4,210,000 per c.mm., white cell count, 8,100 per c.mm., hæmoglobin, 82 per cent, urea nitrogen, 21 mgm per 100 c.c., creatinine, 1.45 mgm per 100 c.c., uric acid, 9.10 mgm per 100 c.c.

On March 3rd, in the fasting state, the blood sugar was 0.277 per cent and the plasma cholesterol was 0.284 per cent. The twelve-hour specimen of urine (8 p.m. to 8 a.m.) showed a volume of 1250 c.c. and contained 15 gm. of sugar. Both acetone and diacetic acid were present, and the total acids corresponded to 820 c.c. of deci-normal (titratable acid plus ammonia).

PROGRESS

In spite of a diet much below the caloric requirements, the urine still contained sugar and acetone bodies five days after the patient's

admission to the hospital, though the blood sugar had fallen from 0.277 per cent to 0.175 per cent. Insulin treatment was then commenced. On March 7, he was given ten units of insulin and the following day the urine was free of sugar and the amount of acetone bodies had decreased. The next day (March 9), the blood sugar was 0.147 per cent.

On March 10, the patient complained of a sharp pain in the left foot, involving the great toe and metatarsal region. The toe was then found to be red, hot and tender, with the typical gouty appearance. At that time he attributed the attack of gout to the insulin. Little attention was, however, paid to this possibility at the time. He was given atophan treatment, and by March 19 all acute signs, both subjective and objective, had disappeared, with the exception of "a little pain in the toe." With the attack of gout there was some disturbance in the course of the diabetes, in that glycosuria and acetonuria reappeared, and it was necessary to increase the dose of insulin to thirty-five units. Twenty units were given in the morning before breakfast, and fifteen in the evening before dinner. In a short time, however, with the disappearance of the acute symptoms of the gout, it was possible to reduce the dose and, on discharge from the hospital, on March 26, the urine was free of sugar and contained no acetone bodies. The blood sugar was normal (0.118 per cent). The plasma cholesterol was 0.194 per cent and the uric acid was 3.63 mgm per 100 c.c. of blood. He was then tolerating a diet of 50 gm. of carbohydrates, 150 gm. of fat, and 50 gm. of protein on fifteen units of insulin a day, taking ten in the morning and five in the evening. He weighed 126 lbs. There was still some pain in the affected toe. At that time the patient, a very intelligent individual, remarked that this was the first attack during which the pain had continued for so long a time.

He was again seen on April 27, and gave the following history* —

Until April 21, he took the same doses of insulin as on discharge from the hospital, namely, ten units in the morning and five at night, *but not daily*. The pain in the toe had not disappeared and, since the progress of the gout differed from all previous attacks, he again considered the possibility that it was due to the insulin. Insulin was, therefore, discontinued about three days a

*Importance was attached to this history because of the intellectual capacity of the patient, his knowledge of his diet, and recognition of the part that it played in the control of his diabetes, and his co-operation.

week He then noticed on the days that he was receiving no insulin, he was free of pain In order, however, to keep the urine sugar free he, without instructions, reduced his diet, and was living on approximately 25 gm of carbohydrates, 80 gm of fat and 30 gm of protein per day

On April 27, the urine was sugar free and contained no acetone bodies The blood sugar was on the border-line of hyperglycæmia, namely, 0.128 per cent The cholesterol was 0.250 per cent and the uric acid was 7.50 mgm per 100 c c

Since his discharge from the hospital (March 26), colchicum and atophan both were of little

value in controlling the residual pain His weight was now 116 lb On the low caloric diet he lost 10 lb On April 29 his diet was increased and it was suggested to him that he take small doses (5 units) of insulin daily With this the pain became very acute the following day Insulin was then discontinued In order, then, to keep the urine sugar-free, he was given the dietary treatment of pre-insulin days that is one in which both the carbohydrate and caloric contents were gradually increased Notes of farther progress are recorded in the accompanying table

TABLE

Date	Blood Sugar Per Cent	Urine Sugar	Urine Acetone	Plasma Cholesterol	Blood Uric Acid mgm per 100 c c	Remarks

Sept 1,	0.119	0	0	0.333	6.65	Weight, 120

It will be seen that on May 5 the urine was sugar-free, but contained traces of acetone bodies and the blood sugar was normal (0.111 per cent). The uric acid was 6.66 mgm per 100 c.c. He was seen again on May 14 and, at that time, conditions were practically the same as those on May 5. The blood sugar was 0.098 per cent. His weight, however, was only 117 lb. and, though he was free of gouty pains, he had the appearance of a diabetic of the pre-insulin days. The plasma cholesterol was 0.262 per cent.

Since the blood sugar was normal, he was given a diet consisting of 50 gm. of carbohydrates, 150 gm. of fat and 50 gm. of protein. This was consistent with his requirements. One week later, on May 21, though the urine was still sugar-free the blood sugar was 0.166 per cent. The rise in the blood sugar suggested that the diabetes could not be kept in an ideal state of control without insulin. On June 4 this became more apparent, since the blood sugar had risen to 0.186 per cent, though the urine was still sugar-free. The uric acid was 5.42 mgm per 100 c.c. An attempt was then made to use synthalin. The experimental nature, and probable failure, of this treatment was explained to the patient and he offered his co-operation.

He was given 25 mgm of synthalin every second day and on June 11, his weight was 119 lb., and the urine was sugar-free and had remained so all of the previous week. The uric acid was 4.63 mgm per 100 c.c. and the blood sugar was 0.140 per cent. He stated that he had diarrhoea on two occasions during the week and that he had mild cramps. Because of the latter complaints a van den Bergh test was performed on the blood and the urine urobilinogen was estimated. Neither showed evidence of liver damage. He was warned about the possibility of these symptoms, but did not think they were bad enough to discontinue the use of the tablets, because he was "in the hope that they might do good." On June 18, one week later, the blood sugar was 0.129 per cent and the uric acid 5.74 mgm per 100 c.c. He was still taking 25 mgm of synthalin every second day. On June 25, the blood sugar was practically normal (0.125 per cent), the cholesterol was 0.333 per cent, the uric acid was 4.90 mgm per 100 c.c. and the urine was sugar-free. On July 25 and August 13 the blood sugars were 0.135 per cent and 0.111 per cent, respectively, and there was nothing relevant to report during these visits. It will be noted that the plasma cholesterol was high on both occasions.

During the last visit he stated that he had no gastro-intestinal upsets since those complained of on June 11. He returned again on September 10, feeling well and looking well, and stated that he had had no supply of synthalin for the previous day. The urine was sugar-free, but the blood sugar was 0.145 per cent and the plasma cholesterol was 0.333 per cent. At that time he weighed about 122 lb., and stated that he felt better than before he had his diabetes. He was given more synthalin. On October 1, 1927, the blood sugar was 0.108 per cent and the other findings were irrelevant. On November 5, he returned and stated that he had had no synthalin supply since October 30, and he also said that he had not felt so well for five years. The blood sugar at this time was 0.143 per cent. The plasma cholesterol was 0.286 per cent. On December 31, he again returned because he had had no synthalin since December 24. The blood sugar was then 0.200 per cent. He was given neosynthalin and told to take 10 mgm per day, and has done so since. The subsequent findings to date are recorded in the table above. It will be seen that, except on two occasions (January 14 and March 10, 1928), the blood sugars were normal.

It will thus be observed that, for about fifteen months, the diabetes has been kept under control with the use of synthalin. That the synthalin was essential may be observed from the history of the diabetes while he was in the hospital, and the fact that, on the days when he returned for further supplies with a history of having had none for some days previously, the blood sugars had definitely increased.

COMMENT

Of the two other diabetics in our clinic with gout, in one case the diabetes is mild, and in the second case insulin is necessary. In the latter case, insulin, though given in much larger doses, and over longer periods of time, has not precipitated any attacks of gout. This patient, unlike the one described here, has no albuminuria. That insulin was the exciting factor in precipitating the attacks of gout in the case reported appears to be definitely proved, for when it was discontinued the pain would subside, and when it was given the pain reappeared. The explanation of this phenomenon is rather difficult. In view, however, of the observation that insulin produces oedema of the body tissues in some diabetics, and in view of the albuminuria and also of the recent observations of Folin, Berglund

and Derick¹, in their experimental study of gout, it is suggested that the oedema produced by the insulin does not escape the kidneys, and this may be responsible for the attacks of gout

SUMMARY

A case of diabetes and gout is reported. It was found that insulin precipitated attacks of gout. Unfortunately, it was also found that the diabetes was sufficiently severe to require insulin, that without the latter, and on a diet compatible with the normal requirements, it was not possible to keep the urine sugar-free and the blood sugar normal. Because of this, synthalin treatment was attempted. For a very short period the results were discouraging, in that cramps and diarrhoea appeared. At that time, however, there was no evidence of liver damage. The van den Bergh test was negative and there was no excess of urobilinogen in the urine. For this reason, and also because of the patient's co-operation, it was considered advisable to continue the attempt. The results were successful and continue to be so. For more than fifteen months the urine has been kept sugar-free and the blood sugar practically normal without the use of insulin.

A disturbing feature is the persistence of a high plasma cholesterol. It will be noted that, *unlike insulin, synthalin has had no effect on the metabolism of this lipid*. As a matter of fact, the cholesterol is now higher than when the patient was first admitted to the hospital.

That the condition is an anomalous one is suggested from the fact that one other diabetic with gout, who has been receiving much larger doses of insulin, and over a much longer period of time, does not present the same complication. A possible explanation of this condition is suggested.

RELATIONSHIP BETWEEN GOUT AND DIABETES

No definite causal relationship has, as yet, been proved. The literature records opposing views. Von Noorden² believes in a definite relationship between the two diseases and quotes in addition to his own experience those of noted English and French writers. He states, however, that severe gout, that is, with skin and joint changes, is comparatively rare, only twelve cases have been found in a series of 6,000 diabetics. Helmut Seckel³, recording the experience in Umber's clinic, also believes in the association of the two diseases. On the other hand, Joslin⁴, with his large experience, states gout has occurred so

seldom amongst his cases that he attaches little importance to it. Bingham* of Boston writes me that he has not met with a case of gout in his clinic of about 1,000 diabetics. Woodyatt*, Allen* and Campbell* of Toronto, also state they have not met with this phenomenon. In view of the greater incidence of gout in England than on this continent, it is of interest to note that neither Lawrence* nor Harrison* have met with such cases. On the other hand, Graham* has seen two. In our clinic, the case reported here is the third met with. In each the gout was severe. The incidence, therefore, corresponds approximately with that recorded by von Noorden. In the view of the latter, it would appear that there is a causal relationship between the two diseases. It can be shown, by applying calculations based upon the "probability of concurrent events," that there are in our clinic more cases than would be expected from the operation of the laws of chance only. Thus, amongst the last fifty thousand admissions to the Montreal General Hospital, there were twenty-six cases of gout, fourteen hundred and fifty-nine cases of diabetes, and three cases of diabetes and gout combined. Therefore, the probability (p_1) of an individual coming to our hospital having gout was $\frac{26}{50000}$. The probability (p_2) of an individual having diabetes was $\frac{1459}{50000}$. The probable incidence (p_3) of gout and diabetes combined was, therefore, $(p_1 \times p_2) \frac{50,000}{50,000} = 0.75$. Since three of such individuals were found, the incidence was $\frac{3}{0.75}$, or about four times as great as would be expected from the operation of chance only.

Osler's textbook of medicine (10th edition) is noncommittal on this point. The statement is made that "metabolism disturbances in gout may be associated with glycosuria." It will, therefore, be seen that the causal relationship between the two diseases is still debatable.

Grateful acknowledgement is due Dr. D. Grant Campbell for his co-operation and the Eli Lilly Company for the continuous supply of synthalin and neo synthalin *gratis* since it was first prepared.

THE SURGICAL GOITRE*

BY T H LENNIE, M.D., C.M., F.A.C.S.,

Vancouver

IN presenting this paper I do not lay claim to any original experimental work, but rather wish to bring to your attention the modern conception of what is called toxic goitre, or hyperthyroidism, laying special stress on its surgical aspect. A great deal has been written during the past few years on this subject, and rightly so, for the treatment of this serious condition has become, or should be by now, fairly well standardized. Most important of all, the preliminary preparations of those that go to operation has of recent times been completely revolutionized, and this, together with the post-operative care, has reduced the mortality rate to within reasonable limits.

The handling of this interesting condition, from the time of the original consultation to the discharge, calls for great patience, sympathy, and understanding. One should take great pains to gain the complete confidence of the patient. A quiet and undisturbed atmosphere is absolutely essential. The patient should have complete confidence that everything is going to come out all right. This state of mind is of course desirable in any pathological condition, but is most essential in hyperthyroidism. To this end there should be the strictest co-operation amongst all those connected with the case. This is particularly desirable at the time of operation. It is not pleasing to see a patient coming into the operating room with those prominent staring eyes, taking in all the details of gowned and masked figures, terrible looking instruments strewn about, and strange objects everywhere, together with a bright and glaring light. It is such a simple thing to cover the eyes and with a few reassuring words convey the patient to a room which is quiet and restful. It only requires a little thought and attention to detail to accomplish this, and the results obtained are gratifying.

Plummer's classification of thyroid enlarge-

ment, in which nine varieties are enumerated, is well known. For practical purposes however Jackson's classification, which follows, is to be preferred.

(1) Colloid goitre, (2) Adenomatous (simple and toxic), sometimes referred to as nodular goitre, (3) Exophthalmic goitre.

As the title of this paper is "The Surgical Goitre" we need spend little time in the discussion of the colloid type. This form of goitre calls for surgery only for the relief of pressure symptoms.

The adenomatous and exophthalmic forms are surgical. The simple adenoma should be operated upon because in about 50 per cent of cases it will become toxic before the age of forty-five. The adenoma with hyperthyroidism demands surgical intervention because of the cardiovascular damage which it causes. In the light of our present knowledge surgical interference offers by far the best results in the treatment of the hyperplastic or exophthalmic goitre. A short discussion of these different types may be of interest.

An adenoma usually develops in a neglected colloid goitre. It is an attempt on the part of the gland to produce an increased amount of thyroxin. The adenomatous goitre is irregularly enlarged.

In the toxic adenoma the onset of symptoms is more gradual and less severe than in exophthalmic goitre. There is usually the history that a goitre has been present for years. The symptoms are nervousness, palpitation, tremor, moist warm skin, and loss of weight which becomes rapid when the hyperthyroidism has become established. Pressure symptoms depend on the size and position of the adenoma. Cardio-vascular derangements are present as a result of the continued toxicity. The heart is usually enlarged. Auricular fibrillation and myocardial degeneration are fairly common. The pulse pressure is increased. The basal metabolic rate is not so high as in

* Presented during the extra mural course conducted recently in British Columbia.

exophthalmic goitre, rarely being above + 60

In contrast to the insidious onset of the toxic adenoma, exophthalmic goitre develops very rapidly. There may or may not be evident enlargement of the thyroid gland. It usually occurs between the ages of 18 and 25 but is by no means limited to these ages. It progresses in waves, with periods of exacerbation and remission of symptoms. These symptoms are tachycardia, nervousness, irritability, emotionalism, exophthalmos, restless movements, fine tremor, heat tolerance, moist skin, and excessive perspiration, dyspnoea, insomnia, loss of strength particularly in the quadriceps, loss of weight, sometimes associated with an increase in appetite. Exophthalmos does not appear at the onset. Gastro-intestinal disturbances do not occur until the disease is well established. Cardiac bruits are frequently present and there is a high pulse pressure. The heart may be enlarged. The basal metabolic rate is usually higher than in toxic adenoma.

On examining suspected cases of hyperthyroidism one must bear in mind that all these symptoms are not present in every case. In one there is increased pulse rate, in another tremor, in another diarrhoea, in another exophthalmos, in another loss of weight. Some show only progressive emaciation. A patient of mine, aged 64 years, with well established toxic adenoma complained only of morning sickness. She would wake up with what she described as a "bilious attack," and was violently ill. Upon examination, however, it was found that there had been a steady and progressive loss of weight, a nervousness extending over some years, an irregular heart, a blood pressure of 170 and 70, and a basal metabolic rate of + 50. Her biliousness stopped, the heart became regular, the blood pressure dropped to 130 to 80 and her weight increased after appropriate surgical treatment.

One might mention here a further class that undoubtedly exists, namely iodine hyperthyroidism. I am convinced that the indiscriminate use of iodine, either as iodized salt or on the prescription of a practising physician, has increased the incidence of hyperthyroidism. This is particularly true of its use in adults above the age of 20. We know that children stand iodine well, and there seems to be evidence that iodine in children will act as

a prophylactic, and possibly will benefit those already showing thyroid enlargement. Its use, however, should be restricted to these two conditions in children, and in adults only as a preparatory measure to operation, and then in the form of Lugol's solution in adequate doses for a limited period of time. We know this, that cases of hyperthyroidism who have had one or more courses of iodine do not respond to this preliminary measure as do those who have never received the drug. Working on the assumption that iodine would change a non-toxic into a toxic adenoma, surgeons were slow to adopt the preliminary iodine treatment in toxic adenomas. At present however practically all goitre clinics are using it in both forms of toxic goitres with, fairly generally, beneficial results. The effect of preliminary iodine administration in hyperthyroidism, particularly exophthalmic goitre, is very startling. The patient becomes more restful, the nervousness diminishes, the pulse rate drops, and the basal metabolic rate comes down, in fact the picture changes completely if only temporarily. We are then not operating on toxic goitres at all, or at least on those showing a much lessened toxicity, and this explains the lowered mortality rate. This clinical change is borne out by the histological picture of the gland removed at operation, the section obtained being one largely of colloid goitre with very little evidence of hyperplasia present.

Since the use of Lugol's solution came in a rapidly decreasing number of thyroid artery ligations are being done. In fact the proper use of iodine has practically eliminated the necessity for ligation. There are exceptional and severe cases of hyperthyroidism, however, which do not respond sufficiently to Lugol's solution, and still require ligation. A ligation tests their ability to stand operation and usually results in a condition of lowered toxicity. In fact, there are cases in which multiple operations are not only justified but necessary, as many as four stages being undertaken. First, one superior thyroid artery is tied, then the other, then a lobectomy is done and finally a second lobectomy. You are all probably familiar with this method, introduced by Crile of Cleveland, and still practised more in his clinic than any other place in the world, but even Crile is finding less reason for this

procedure as time goes on. Let me here pay a tribute to Dr Cile as the pioneer in the attempt to lower the mortality rate for thyroidectomy. At a time prior to the recognition of the efficacy of Lugol's solution, he noticed the disastrous effects of emotional disturbances such as precede an operation upon a toxic goitre. He was the first to suggest removing these painful stimuli.

The introduction of the basal metabolic test has been of great assistance in the diagnosis of hyperthyroidism, in the selection of the time at which to operate, and in the prognosis of the case. A well established case of toxic goitre is easily diagnosed without such a test, though as a confirmation it should always be done. It is in the earlier cases which do not exhibit a greater number of the typical symptoms that this test is particularly valuable, also as a negative finding in cardiac cases which show a rapid pulse and other signs which might be mistaken for toxic goitre. Again, there is the neurotic case who happens to have an enlargement of the thyroid but who exhibits a normal basal metabolic rate. Such will often be saved an unnecessary operation after this test.

The basal metabolic rate is an index of the rate of oxidation going on in the cells of the body. The test should be made after a night's rest, with no food for twelve hours preceding it. The normal in bed cases varies from -10 to $+10$, and in ambulatory cases from -15 to $+15$. The basal metabolic rate is a fair indication of the toxicity of the condition, remembering that in toxic adenoma the rate is not so high as in exophthalmic goitre. It is of great importance to operate on a falling and not on a rising rate. It is more dangerous to operate on the verge of a crisis with a moderately high rate than on a patient with a high rate who has passed the crisis and is improving clinically. The metabolic rate is not necessarily an index to the ability of the patient to withstand operation, of greater significance is a rapid and recent loss of weight, together with a high pulse pressure.

In the June issue of the *Archives of Internal Medicine* an article appears by Segal, Binswanger and Strouse of Chicago on the effect of emotion on basal metabolism. The summary of the paper is as follows:

"1 The effects of the thought of impending operation on basal metabolic rate, blood pressure

and pulse rate were studied in three groups of cases

(a) A constant effect on the rate of metabolism was not seen in group 1, which consisted of patients of various types of nervous stability with a normal rate of metabolism.

(b) In group 2, which was made up of patients with hyperthyroidism who had received iodine according to the present day pre-operative routine, a marked rise in metabolic rate did not occur the day of operation.

(c) Group 3 was comprised of persons with hyperthyroidism who had not had iodine, as in group 2. In these patients a marked rise in the basal metabolic rate resulted the morning of supposed operation.

2 A practical point for consideration is the possibility of using the foregoing procedure as an index of complete or incomplete iodization. A rise of the metabolic rate the morning of operation might indicate that an insufficient amount of iodine had been given."

We have always been sure of the results of preliminary iodine medication but this is the first attempt, to my knowledge, at proving this by experimentation.

PRE-OPERATIVE PREPARATION

Remembering that in toxic goitres there is a burning up of body tissue, which is exemplified frequently by a rapid loss of weight notwithstanding a hearty appetite, it is important that a high caloric diet be instituted, this diet to be particularly rich in carbohydrates. In addition, a large quantity of fluids is administered, and with this a goodly supply of glucose. Rest is absolutely essential and this must be induced by some narcotic. As a preliminary to operation I employ the following régime:

A variable length of time in bed, depending on the extent of the toxicity, is prescribed before the actual preparation for operation. This is as follows:

1 Absolute rest in bed in hospital, preferably in a private room from which visitors are rigorously excluded. During the morning and afternoon the patient is encouraged to sleep by darkening the room and placing a cloth over the eyes. At this point it may be well to repeat the necessity for all the attendants, including the attending medical man, to use the utmost tact and to radiate confidence.

2 At least 100 ounces of fluids in 24 hours Orangeade, sweetened with glucose, between meals

3 A high caloric diet, low in protein, but rich in carbohydrates

4 Lugol's solution, ten to fifteen minims three times a day in one ounce of grape juice or cream

5 Luminal one and a half grams night and morning for the first few days, then at night only, bromides in addition if necessary

6 Ice cap to head

Digitalis is not used unless there are signs of decompensation or auricular fibrillation present, then thirty minims are given every two hours for six doses. In a few days there will usually be a decided clinical improvement, as shown by a lessened nervousness and a lowered pulse rate. This will be demonstrated by an improved basal metabolic reading. This preparation is continued for a period varying from six to fourteen days.

Early on the morning of operation 100 gm of glucose are given in orange juice, and also 20 to 30 minims of Lugol's solution. Three quarters of an hour previous to the operation hyoscine 1/150 gr is given hypodermically, followed in one half hour by morphine gr 1/6 and atropin gr 1/50. This preparation usually assures a moderately calm patient for operation and one who shows very little change in pulse rate during the procedure.

A good deal has been written about the wisdom or otherwise of telling these patients when the operation is to occur. I do not have any hard and fast rule in this regard. Each case must be considered on its merits. Some go into hospital with the understanding that in about a week's time they will be operated upon. Some are notified the day previous to operation. I do not see much difference in this respect providing the pre-operative preparation has been adequate.

OPERATION

Thyroidectomy may be done under local anaesthesia, general anaesthesia, or a combination of both, of the latter, one may employ local anaesthesia up to the point of actual resection of the gland, and then general, or general during the whole procedure augmented by local. As we know, inhalation anaesthetics cause suboxidation, so that deep anaesthesia is

absolutely contraindicated, and this applies particularly to ether. After a little experience in all these different methods I prefer the combination of light nitrous oxide and oxygen, together with local by the infiltration method.

As local anaesthesia appears in all these methods, with the exception of one, it is well to discuss it in detail. The skin of the neck is prepared with alcohol, or mercurochrome 2 per cent. Novocaine, without adrenalin, 1/2 to 3/4 of 1 per cent is injected with a long needle along the line of incision through one needle puncture. Through this same puncture the whole of the anterior aspect of the neck well beyond the sternomastoid muscles is also injected, taking care to keep the needle constantly in motion. This requires a good deal of solution, about 200 cc may be necessary for the superficial and deep injection. The incision is then made and the flaps dissected above and below, being sure to get adequate exposure. The fascia and muscles are then injected on either side of the mid line through about three punctures. These are then incised in the mid line downwards and this incision should extend from the thyroid cartilage to the sternum. The sternothyroid and sternohyoid muscles are then separated and the muscles of the right side retracted by an assistant. The capsule of the right lobe is then injected with novocain. This not only acts as an anaesthetic but lifts the capsule from the gland and facilitates dissection. When the capsule is incised and separated the gland is then injected both in its upper and lower poles. Resection of the lobe is now commenced. A similar course is followed on the left side. While novocain injection may add a few moments to the operation this objection is far outweighed by the lessening of the depth of general anaesthesia and the way in which dissection is facilitated.

Of course, bilateral resection is the universal operation to-day, except where there is a single adenoma. One gets very few recurrences if the greater bulk of both lobes is removed. My practice is to try to leave just a slice of thyroid tissue with the posterior capsule. By the resection method it is not necessary to isolate the superior thyroid arteries, as was the custom in the old days, but a portion of the superior pole is clamped and

tied with these vessels. As there are a great number of clamps used in the resection operation a great deal of tying is necessary, and woe betide the operator who is careless in this regard. After all bleeding points are secured the different layers are sutured separately and a soft rubber drain left in for twenty-four hours. During the operation the patient receives physiological saline interstitially, and before leaving the operating room is given morphine gr 1/6.

On returning to the ward she is immediately given by the rectum 6 oz of saline containing 10 per cent glucose and 30 to 40 mm of Lugol's solution. The saline without Lugol's is repeated every four hours, and ten minims of Lugol's solution are given by the mouth three times a day for three days. It is very necessary that these patients be kept quiet, so that morphine is used liberally gr 1/6 q 2 h if required.

On the second day 2,500 to 3,000 cc of fluids should be ingested. The drain is removed in twenty-four hours after operation, and the skin sutures on the third or fourth day.

If the pre-operative and post-operative routine I have outlined is followed there is very moderate reaction and the patient is usually allowed to get up about the sixth day.

Those cases of acute post-operative hyperthyroidism which were formerly so dreaded are practically unknown since iodine has been used as a preliminary preparation and for seventy-two hours following operation. If during the operation there is evidence of considerable reaction, which is best exhibited by a rapidly increasing pulse rate, the wisest course is to stop, pack, and finish the job later on.

In addition to the above possibility other post-operative complications may occur such as hæmorrhage, post-operative tetany, or hypothyroidism. Pressure and ice caps will help to control oozing. Hæmoplastin may be given with advantage, or it may even be necessary to open the flaps and secure bleeding points. Mild post-operative tetany will be controlled by calcium lactate by mouth or subcutaneously, or if these fail, by parathyroid extract subcutaneously.

A mild hypothyroidism may follow a very radical operation. Unless all the gland has been removed this is usually controlled by small doses of thyroid extract, which usually need not be continued for long.

In the resection operation injury to the recurrent laryngeal nerves should be a very rare occurrence. Injury to one nerve is not very serious, but injury to both nerves is a catastrophe and calls for immediate tracheotomy.

SUMMARY

I have endeavoured in this short paper to emphasize a few points which seem to be of paramount importance in the successful treatment of hyperthyroidism and in summary would mention

- 1 The importance of gaining and holding the confidence of the patient
- 2 The necessity for exclusion of all irritating and exciting influences
- 3 The absolute indication for an adequate and careful preliminary preparation
- 4 The desirability of guarding against sub-oxidation by using light anaesthesia
- 5 The importance of removing an adequate amount of thyroid tissue

Case of Magnesium Sulphate Poisoning—Harvey S. Thatcher reports the case of an American farmer, aged 26, poorly nourished, who had a provisional diagnosis of psychoneurosis of the neurasthenic type. At 6 a.m. he was evidently accidentally given a dose of magnesium sulphate. He was found dead at 7.10 a.m. Approximately 1 litre of yellowish brown fluid was present in the stomach and a dark red and hæmorrhagic appearance of the lining of the stomach and small intestine, and considerable blood was mixed with the contents. The chemist reported 883½ grains (57 grm) of magnesium sulphate in the contents of the stomach.

As the dosage is 240 grains (15.5 grm) the amount recovered was more than three times the required dose. The case reported illustrates that more care should be exercised in the administration of magnesium sulphate. Toxicity may result without death. An idiosyncrasy may exist and the average dose may be toxic. If toxicity does occur after its use, the treatment consists of the subcutaneous or intravenous administration of calcium salts, according to Meltzer and Aner. There is an antagonistic action of calcium on the inhibitory effect of magnesium.—*J. Am. M. Ass.*, 1928, vol. 1185.

DISSEMINATION OF THE BROAD TAPEWORM BY WILD CARNIVORA*

BY TEUNIS VERGEER

*University of Michigan,**Ann Arbor, Mich*

IN a paper to appear in the *Journal of the American Medical Association* I have pointed out that the dog in the northern lake regions of Alberta, Manitoba, and Ontario is an important reservoir of the broad tapeworm of man. There the wall-eye and great northern pike, *Stizostedion vitreum* Mitch and *Esox lucius* L., respectively, are infested with broad tapeworm larvae and are fed raw to dogs. The dogs live at or near water, so that the eggs of the adult broad tapeworms, *Diphylllobothrium latum* L., with which they are infested, readily get into the lakes and streams and make possible the reinfestation of the fish. Since numerous experiments have proved that dogs very easily acquire broad tapeworm infestations,¹ it is probable that the early reports² of broad tapeworm from dogs were actually correct, and it is possible that the immature *D. americanum* reported from a dog in Detroit by Hall³ is *D. latum*.

In a paper appearing in the *Journal of Infectious Diseases* I have called attention to the possibility that some wild carnivores might also serve as carriers of the broad tapeworm of man and might constitute a factor in the maintenance of infestations in fish capable of harbouring the larvae. Waithin⁴ reported a broad tapeworm from a wild fox, probably *Vulpes fulvus* (Desmarest), from northern Michigan, and, since in general the parasites which infest the dogs also infest foxes, foxes in endemic areas must therefore be considered as factors in the dissemination of this tapeworm. That the grey wolf,⁵ *Canis occidentalis* Richardson, and the coyote,⁶ *Canis latrans* Say, are known to feed on fish is reported by Ernest Thompson Seton in his most interesting and detailed work on the life histories of northern animals. One grey wolf

was reported to have taken fish from a fisherman's net while set through the ice. Since wolves and coyotes are common in the endemic regions of Canada it is obvious that they must also aid in the maintenance of the infestations with *D. latum*. German workers have reported broad tapeworm from cats⁷ and I have experimentally infested one domestic cat with a broad tapeworm.⁸ It is well known that cats like fish, and in infested areas domestic cats doubtless have broad tapeworm.

Since the lynx, or bob-cat, *Lynx canadensis* Kerr belongs to the same family as the domestic cat and is much larger, it is only reasonable to assume that the broad tapeworm can develop in its intestine. The lynx feeds mostly on small mammals and birds, varying its diet from time to time with fish⁹ and frogs. It likes water and will voluntarily swim distances of two miles.¹⁰ The lynx is common in infested areas in Canada and occurs in northern Minnesota and Michigan. It seems entirely probable that this animal occasionally harbours broad tapeworm and, because it often lives near water, may thus aid in the maintenance of the infestation in fish. Whether mink, martin, raccoon, fisher, and otter, all of which subsist wholly or partly on fish, are capable of becoming infested with broad tapeworm is not known. Since in cats the broad tapeworm is smaller than in other known hosts, and in dogs it is always smaller than in man, it seems that small size of the host may be a factor limiting the development of this tapeworm. The mink and martin are smaller than the house cat. Therefore it is difficult to believe that they can harbour *D. latum*. The fisher, otter, and raccoon are all larger than the cat, and experiments might show that they can serve as hosts of *D. latum*. However, none of these seem to be abundant in endemic areas, either in Canada or in the United States, while foxes, coyotes, wolves, and lynxes are rather

* Contribution from the Department of Zoology, University of Michigan. One of a series of investigations carried on under grant 131, awarded by the American Medical Association to Professors George R. La Rue and A. S. Warthin of the University of Michigan, under the former of whom the work has been conducted and to whom I here express my grateful appreciation.

common in Canada and not rare in upper Michigan and Minnesota

The largest carnivore in America is the bear. It is not closely related to either the cat or the dog family. In its food habits it more closely resembles man than either the dog or the cat, since it eats berries, roots, and herbs in addition to animal food. If the broad tapeworm of man can develop in bears, the latter may be capable of harbouring much larger numbers of broad tapeworms of greater size than the mammals before mentioned, because of the diameter of the lumen and the length of their intestines. Unknown adult "bothriocephalid tapeworms" have been collected by Waid¹¹ "from bears in the northwestern United States and in Alaska and the larval stages of these cestodes in salmon in those regions". It is not reported that feeding experiments were performed. Bears have been reported by naturalists to stand in shallow streams and to scoop out fish as they come up to spawn. Such observations are confirmed by woodsmen whom I interviewed last September in the forest region northwest of Lake Superior. Here the wall-eyes and great northern pike crowd up the shallow streams to spawn, and bears by the sweep of a paw throw the fish on land. One man reported to me that he had seen a bear throw out twenty fish before it began to eat them. Seton¹² mentions spawning fish as a regular food supply of bears. It is only while spawning that fish are easily caught by bears. Just at that time all other food is scarce, and it is very possible that not only bears but also other carnivores, driven by hunger, "go fishing" or at least pick up stranded fish. Bears like water and they swim long distances. I have personally found signs of visiting bears on small islands from a half to a mile from shore. There were trees from which bears had pulled the bark and also old stumps and trunks which they had broken in pieces in search of grubs and ants.

Because bears eat considerable quantities of fish, like to be in the water, and live in numbers in areas where I have found the fish infested with larvae of the broad tapeworm, and because they can probably harbour more and larger adult worms than any other mammal in North America, including man, it became a matter of importance to determine whether the bear could

actually and readily become infested with the adult *D. latum*. For this purpose two young bears of the species *Ursus americanus* Pallas were obtained. One was a cinnamon coloured male, the other a black female. Each weighed approximately 100 lb. They had been caught in Canada as "nursing babies" and reared "on the bottle". Immediately after weaning they were shipped to a city in western Michigan where they had since been fed exclusively on bread and milk. Their keeper states positively that they had never tasted fish or meat. Faecal examinations proved that they were free from parasites. Eight plerocercoids which I had taken out of six wall eyes from Thunder Bay, Lake Superior, and had identified as *D. latum* were fed to the cinnamon bear in pieces of muscle of the fish. Uninfested muscle of the same fish was first offered to this bear and he spent considerable time investigating the fish by smelling, pawing, licking, and finally taking it in his mouth. These actions indicated that the bear was not acquainted with fish food. Once having tasted the fish, the bear wanted all he could get. Each of the eight plerocercoids in a separate piece of fish was fed to this cinnamon bear after which he was allowed to eat his breakfast of milk-soaked bread.

For the black bear ten plerocercoids, identified as *D. latum*, were taken out of twenty-five specimens of wall-eyes from Lake Nipigon. Some uninfested pieces of fish from the same lot were offered to the black bear but continually refused, demonstrating that this bear did not know the taste or odour of fish and was not interested. It confirmed the keeper's statement that the bear had never had fish. Beef was offered her afterward and it was also refused. The bear was starved for twenty-one hours, and again fish and meat were offered but refused. Some dry bread was fed to the bear and afterward four plerocercoids, each embedded in a separate piece of milk-soaked bread, were readily taken. Thereupon she received a regular meal of bread and milk. Two hours later another plerocercoid was offered in milk-soaked bread, but the bear was not hungry and refused to take it. Finally, the six available plerocercoids were offered embedded in chocolate cake and no further difficulty was experienced, the bear eating them readily. Faecal samples were taken twenty-three and

twenty-four days after the feeding of plerocercoids. Eggs characteristic of the broad tapeworm of man, *D. latum*, were identified in the faeces of each of the bears and were especially numerous in the faecal material of the black bear. I had previously found in feeding experiments with dogs that plerocercoids did not establish themselves so readily when fed to a hungry animal as when fed about two hours after a meal, and I have obtained 100 per cent infestations by the last procedure. This probably accounts for the especially heavy infestation in the black bear. The infested bears are being kept for further study.

By means of these experiments I have proved that bears readily become infested with the broad tapeworm of man. They also give strength to Ward's¹¹ suggestion that the species from man may be the same as the species of bothriocephalids which he recovered from bears in the northwestern United States and Alaska. In the forested lake regions of Canada I found the plerocercoids of the broad tapeworm of man common in wall-eyes and great northern pike and found that bears were common in the woods. Bears will continue to increase in numbers as long as their skin is of little commercial value. Nowadays trappers feel that there is no profit in taking them. In northern Michigan where fish are infested with broad tapeworm larvae⁶ bears are protected and increasing rapidly, if one can judge by claims for damage to livestock by bears. These claims, according to figures compiled by the state conservation department, amount to \$6006.90 for the fiscal period between July 1927 and July, 1928.

Since bears are common in regions where fish are infected with broad tapeworm larvae and since they eat a great deal of fish during the spawning season, it is evident that bears in these regions must have broad tapeworm. With their excrement they drop large numbers of broad tapeworm eggs daily. Many of these get into the water directly because, as before mentioned, the bear is a lover of water, likes to bathe and swim, and fishes while standing in it. In this manner the eggs hatch readily and eventually the fish in the lakes become re-infested.

From the evidence presented above it is clear

that the infestation of fish with plerocercoids of broad tapeworm is partly beyond control of man. It is virtually impossible to prevent wild carnivores from eating raw fish. The extermination of our wild carnivores to prevent the infestation of fish with plerocercoids of *D. latum* is unthinkable. All of these considerations clearly point to the conclusion that, in order to protect man from the broad tapeworm, it will be necessary to devise adequate means of killing the larvae before fish is eaten, and preferably before the fish reaches the consumer.

SUMMARY

The dog, the fox and the cat are known to serve as hosts of the adult broad tapeworm of man. Because of family relationships it is safe to assume that the wolf, the coyote and the lynx are also capable of serving as hosts. Since all of these eat fish, they in all probability are factors in the dissemination of broad tapeworm in regions where fish are infested with the larvae.

Bears are common in infested territories and catch and eat fish during the spawning seasons. Two bears have been experimentally infested with *D. latum* and thus the bear has been shown to be a very capable host of the broad tapeworm of man. The abundant bears in infested territories must constitute a considerable reservoir of broad tapeworm. Since they like to be in and about water, their egg-laden droppings must cause considerable reinfestation of the fish.

Because wild carnivores disseminate broad tapeworm the infestation of fish with broad tapeworm larvae cannot be completely controlled by man.

Case Reports

A CASE OF MENINGOCOCCAL SEPTICÆMIA OR SPOTTED FEVER

By W D HAY, M A, M D, AND
P H HUICK, M D,

*Richardson Laboratory, Queen's University,
Kingston*

A school boy of thirteen years was going about as usual on Saturday morning, June 9, 1928. He went on his bicycle to a store which was three miles away, and after returning took his ordinary mid-day meal. About 2 o'clock in the afternoon he complained to his mother that he felt tired and that his arms and legs were stiff and sore. By 6 o'clock his condition was not improved and he complained further of headache and pains in the back. Later on in the evening he vomited. When some of the members of the family returned from the city, about 10 o'clock, he got up and examined the purchases which had been made. About 12.30 o'clock his condition became so alarming that medical aid was summoned. When seen shortly after 1 o'clock the boy's temperature was 104°, pulse 160, and scarcely perceptible. He died about 5 o'clock, after an illness of fifteen hours' duration. Just before death the pupils became widely dilated, the head somewhat retracted, and there was some stiffness in the limbs. A diagnosis of meningitis was made by the attending physician. No history of any recent illness could be obtained from the parents.

An autopsy was performed while the body was still warm. There were several petechial hæmorrhages into the skin over the legs, arms and face. Similar hæmorrhages were found under the visceral pericardium. The heart was otherwise normal. There were extensive hæmorrhages under the pleura of both lungs. The lung tissue was intensely congested. The spleen was somewhat congested and soft.

The brain and meninges were markedly congested. The spinal fluid was clear. There was no apparent exudate into the subarachnoid space.

Cultures of meningococci were obtained from the base of the brain, the naso-pharynx, the heart's blood, and the spleen. These organisms

were agglutinated by the polyvalent meningococcus serum prepared by the Connaught Laboratories.

The microscopical findings were as follows. Hæmorrhages were present in the pleura. The smaller bronchi were filled with desquamated cells and leucocytes, and amongst these could be seen masses of organisms. Some of these were streptococci, others diplococci with the morphological and staining characters of the meningococcus. The spleen showed congestion, hæmorrhages were present in the pulp, and there were necrotic foci in the Malpighian bodies, but no organisms could be found. The kidneys, liver, and heart showed intense cloudy swelling. The brain showed no evidence of exudate or cellular infiltration of the meninges. The only microscopical change was congestion.

DISCUSSION

This is an example of the septicæmic type of meningococcal infection with only slight involvement of the central nervous system. Wooster-Drought and Kennedy* quote a case in their book on cerebro-spinal fever of a child dying after an illness of thirteen hours only. The fact that no outbreak of this disease had occurred in the district for a considerable time made the diagnosis difficult. The chief diagnostic findings are, the sudden onset of acute symptoms, and the presence of cutaneous hæmorrhages, with or without evidence of meningeal irritation. It is useless to wait for a bacteriological diagnosis before giving serum when the patient presents these symptoms. Experience shows that in these acute cases the intravenous administration of serum is just as necessary as the intrathecal treatment.

Eighty-five persons who had been in contact with this boy were examined in the Richardson Laboratory, and it was found that the father and one of the other children were carriers. In fact, the swabs from the naso-pharynx of the father gave almost pure cultures of the meningococcus. These organisms were agglutinated (1-40) by the Connaught Laboratory serum. The two carriers were treated with serum. It is interesting to note that both

* Cerebro Spinal Fever, Wooster Drought & Kennedy, A. C. Black, Ltd, London, W 1, 1919.

suffered severe serum reactions from the 8th to the 12th days, and that in both cases the organisms rapidly disappeared during this period

A CASE OF CO-EXISTING BENIGN ŒSOPHAGEAL AND PYLORIC STENOSIS

By WILFRID L. GRAHAM M.B., F.R.C.S. (Ed)
AND W. H. HATFIELD, M.B.

Vancouver

The following case has been thought worthy of reporting on account of the rarity of an Œsophageal obstruction being associated with a pyloric stenosis, furthermore the Œsophageal obstruction is of interest from an etiological standpoint, the common causes being here excluded

CASE REPORT

Present Illness—Mrs W. Y., aged 40, Canadian housewife, came into the office on November 14, 1927, complaining of loss of weight and attacks of vomiting. Previous to Christmas, 1926, the patient had been in fairly good health, though always troubled more or less with "indigestion". At this time she began to have water-brash and a sense of fullness in the epigastrium, with occasional attacks of vomiting which usually came on one or two hours after meals. The vomiting was not associated with pain. These symptoms persisted to some extent until June, 1927, when her vomiting became more persistent and was of a projectile type, but as before was not associated with nausea or pain. Her weight up to this time had remained constant at about 130 lb. As the vomiting became more severe, the vomitus assumed a black appearance, and her physician found that there was blood in the stool. In August she began to experience a slight difficulty in swallowing and the vomiting occurred almost immediately after meals.

The patient was admitted to hospital at this time, where she remained for three months under her physician's care. No barium series was done, the case being considered an inoperable carcinoma of the stomach. During this period she lost weight rapidly and her vomiting was not controlled. Her weight on discharge in August was 80 lb., and she was given to understand that her prognosis was hopeless. The patient found that she could retain small amounts of fluid if

taken at frequent intervals, but could not take solids as they were almost immediately regurgitated. On a strictly fluid diet her vomiting stopped and her weight slightly increased. For the next month the patient remained fairly comfortable, but she was unable to change her fluid regime, even semi-solids initiating vomiting. The difficulty in swallowing had increased. From October until seen by us in November she had not vomited, but was beginning to lose weight again. When seen on November 14th, 1927, her weight was 81 lb., and she was cachectic in appearance and very weak.

Past History—On close questioning, the patient gave a typical history of a peptic ulcer which had its origin about twenty years ago. The history was disconnected but definite. She stated that five years ago her pain following meals disappeared and she remained in good health until the beginning of the present illness. She had had influenza in 1926.

The *Family History* was unimportant.

Physical Examination—An emaciated cachectic-appearing woman of about middle life. Apart from her abdomen the physical examination was negative, except for a fairly large non-toxic adenoma of her thyroid.

The abdomen appeared full, the skin inelastic and dry. A fluid wave could be elicited across the whole abdomen, with a definite splash most marked in the region of the umbilicus. Resonance was normal in the loins. There was no rigidity and no palpable mass, but a tender point was present in the region of the pylorus. The liver, spleen, and kidneys were not palpable. Rectal and pelvic examinations were negative.

Laboratory Findings—Red blood cells, 2,500,000 per cmm. Hemoglobin was 45 per cent. The smear showed the picture of a secondary anemia. Urinalysis, negative. A subsequent stomach analysis showed no free acid. A barium series revealed a very large atonic stomach with the lesser curvature at the level of the iliac crests (See Fig 1), with an almost complete pyloric stenosis. Malignancy was considered but was excluded on account of the appearance of the x-ray.

The patient was admitted to hospital on November 16, 1927. A Rehfuß tube was passed and an unsuccessful attempt was made to aspirate the stomach contents. A considerable amount of water was injected through the tube, but only a small part of it could be recovered. The question of an Œsophageal occlusion was then

considered and the fluoroscope revealed the fact that the Rehfuß tube lodged about $1\frac{1}{2}$ inches above the diaphragm. A heavy barium paste was then given and showed that the oesophagus filled up to this point, the lower margin of the barium was cone-shaped (a rather long pointed cone), but below this a very narrow shadow of barium was seen, extending downward into the stomach, the calibre of the shadow being little more than that of a knitting needle. The exact nature of this blockage was not obvious at this time. (See Fig 2)

FIG 1—Pyloric stenosis. Extreme ptosis of the stomach, the lesser curvature being on a level with the iliac crest.

It was apparent that there was an obstruction practically occluding both ends of the stomach, a pyloric stenosis, certainly benign, due to a healed pyloric ulcer, and an oesophageal stenosis of unknown origin.

The first problem was obviously the oesophageal stricture, and with this in view Dr F W Brydone-Jack was asked to do an oesophagoscopy. This, performed under local anaesthesia, on November 23rd, 1927, revealed a stricture of the oesophagus, with no ulceration and no hyperkeratosis of the oesophageal mucous membrane. A dilatation of the stricture was partially accomplished at the first attempt, and a gum-elastic feeding tube was inserted into the stomach. The

stricture involved about three inches of the oesophagus. The stomach was then aspirated and for the following week the patient was kept on a high caloric fluid diet injected through the tube, with a nightly aspiration of the stomach. Intravenous glucose and hyperdermoclysis were also used. At the conclusion of the week the patient had gained $9\frac{3}{4}$ lb, a great deal of which, of course, was due to her increased fluid intake. Her general appearance, however, was very much improved.

On November 30th a second dilatation was done and a Rehfuß tube was passed into the

FIG 2—Oesophageal obstruction involving the lower three inches of the oesophagus.

stomach. Following this the patient was able to swallow fluids, and, with a nightly aspiration, she was kept fairly comfortable. The aspiration was made necessary by the atony of the gastric wall, resulting from the overdistension caused by the weight of the fluid which had remained so long in the stomach, this could neither pass down, nor could it be vomited up, owing to the pyloric stenosis on the one hand and the oesophageal occlusion on the other. The patient was discharged on December 2nd, 1927, weighing 95 lb, a further gain of four lb.

On December 5th the patient reported to the office, feeling much stronger. Dr Brydone-Jack again passed an oesophageal No 14 bougie, and found that the stricture had shown no

tendency to recur. The patient was kept under observation for the next month and her general condition rapidly improved. The diet consisted mainly of fluids of a high caloric value, and the tone of her gastric musculature was rapidly recovering, as visualized under the fluoroscope. The gain in average weekly weight was about four pounds, and on February 6th her weight was 118 lb., and she felt in better health than she had for years.

She had now gained enough strength to permit of a posterior gastroenterostomy being done.

Exploration revealed a stomach of fairly normal tone, with the scar of a healed ulcer on the pyloric ring. The stenosis was almost complete. In view of the possibility of the oesophageal stricture recurring, the transverse mesocolon was sutured well back from the stoma on the posterior gastric wall, so that if a hypertonicity resulted there would be no obstruction to the stoma by its being drawn up into the lesser sac. Recovery from the operation was uneventful and the patient was discharged three weeks later. On September 10, 1928, she reported in excellent health, she had no gastric symptoms and was able to take an ample controlled diet.

COMMENT

This case should impress on our minds two essential points: first, the necessity of a routine fluoroscopic examination of the oesophagus in all cases in which a barium series is being done, and, secondly, the importance of a careful history-taking. In reporting this case we are holding no brief for ourselves in the fact that a complete clinical diagnosis was not made. In retrospect one can easily follow the course of this woman's history, beginning twenty years ago with a peptic ulcer, through fifteen years of a fairly typical history, the development of a pyloric stenosis with its attending emesis, the development of an oesophageal stricture, which first interfered with swallowing, then later caused a different type of vomiting from that which previously had been present, and finally the inability to vomit gastric contents due to the stenosis.

Having excluded carcinoma and cardiospasm, both on the evidence of the x-ray pictures and of the oesophagoscopy, one is at a loss to explain this type of benign stricture. It did not have the appearance of a hyperkeratosis, such as was indicated in the cases recently reported by Dr. F. N. G. Starr, of Toronto, nor did it have

the appearance of a stricture resulting from one of the common poisons.

Another point that might be emphasized is the importance of giving a patient the advantage of all modern facilities, especially the x-ray, and, in this type of case the oesophagoscope. We were able by these means to give a good prognosis in a case which appeared from the clinical point of view to be hopeless. Even an exploratory laparotomy should be done before considering a case as being beyond hope.

TWO CASES OF CANCER OF THE LUNG*

By THE MEDICAL STAFF OF THE MOUNTAIN
SANATORIUM,

Hamilton, Ont.

CASE 1

The clinically remarkable features of this case are the long duration of the illness, the lack of symptoms other than hæmorrhage, the afebrile course of the disease, and the relative obesity of the patient. The pathologically remarkable features are the presence of spontaneous pneumothorax, the occurrence of atelectasis, the relatively benign character of the tumour, and the presence of bronchiectasis distal to the tumour.

History of Illness.—Mrs. J. W., 43 years of age, with five healthy children, no occupation other than her home. There was no history of exposure to tuberculosis nor of cancer in the family. She insisted that she had had no previous illnesses and had always been strong and healthy. Her final illness began about six years before death with an attack of pain in the left side of the chest, with cough and sputum, and a hæmoptysis of moderate amount. She remained in bed only a few days, and stated that she had night sweats with fever at this time for two or three weeks. About three weeks later, she had a second hæmoptysis amounting to half a cupful and a year later three of like size. From this time on the hæmorrhages increased in frequency but her general condition remained good. She felt well and continued at work. In March, 1927, hæmoptyses occurred almost daily and averaged about two ounces in amount. She came to the Mountain Sanatorium on April 12, 1927, and remained until June 4, 1927. While there her

* Reported by Dr. T. G. Heaton.

illness remained afebrile and she had no cough or sputum. She went home on light exercise and was re-admitted on October 31, 1927, following several hæmoptyses. She was kept in bed and remained free of hæmoptysis after this until February 9th, 1928. During this admission also her illness was afebrile. She had occasional morning cough with a little sputum, and complained of no other symptoms. On February 9th the hæmoptyses became frequent and severe. On February 14th, an attempt was made to control them by artificial pneumothorax. The right pleural cavity was entered in several places but manometer readings of minus 40 to plus 60 were obtained. No air was put in. Next day an x-ray of the chest confirmed the diagnosis of right-sided pneumothorax. There was no loss of weight at any time during her illness and she remained moderately obese.

On February 16th, the patient died of hæmorrhage with aspiration of blood.

Physical Examination — The patient was cyanosed for several days after her second admission. When this cleared up, her appearance was healthy. The chest showed slight impairment of resonance at the right base anteriorly and posteriorly. Medium and coarse râles were heard at the left base on admission. These persisted.

The first x-ray examination was made by Dr L. R. Hess in March, 1927, and his report at that time read in part as follows:

"This film shows the characteristic partial collapse of the right lung with elevation of the diaphragm, retraction of the heart and mediastinal contents and deviation of the trachea to the right due to a foreign body, (aspirated blood) in the bronchus."

Second films were taken at the Mountain Sanatorium on April 12, 1927, and showed less contraction of the lung field on the right side than those taken in March. This report read as follows:

"The left dome of the diaphragm is normal, the angles are clear. The left cardiac border is more oblique than usual. The right cardiac border is not clear. There is an irregular triangular-shaped area of homogeneous shadowing filling in the angle between the right dome and the bodies of the vertebrae. The apex of this extends to the third rib anteriorly. The

interpretation of this area is doubtful. Extending out from this in the third and fourth interspaces there is a little scattered medium mottling. The paravertebral trunk in the right lung extends into the upper two-thirds of the apex. The linear markings in the right lung in the first and second interspaces are a little heavier than average. In the left lung the linear markings are a little heavier than average below the third rib."

An x-ray picture was taken on June 6th following the introduction of lipiodol. This did not show bronchiectasis, but the lipiodol had not passed the obstruction in the bronchus to the lower lobe. Later, part of the lipiodol must have got by the obstruction as it was found distal to the tumour at autopsy.

Anatomical Diagnosis at Autopsy — Cancer of the lung, (bronchogenic, right lower lobe), hæmorrhage into the lungs, rightold pleural adhesions, right lower bronchiectasis, distal to the tumour, old atelectasis and fibrosis of right lower lobe, lipiodol in bronchiectatic cavity, tuberculosis of right pleura (healed), right spontaneous pneumothorax, atelectasis of left upper lobe, old peritoneal adhesions, multiple leiomyomata of the uterus, pigmentation of the large intestine, hyperplasia of lymphoid tissue of the large intestine.

The right lung measured 19 x 12 x 6 cm. and weighed 16½ ounces. The pleural surface bore a fibrous tag at the apex and numerous tags about the base of the lung. The surface of the lung was puckered at the apex, and here a large bulla of air 1 cm. in diameter was present. A spot on the posterior surface of the lung was roughened by a cluster of four or five small yellowish firm nodules of less than 1 mm. in diameter. The anterior half of the lung was pinkish yellow in colour, marked by a loose network of gray anthracotic pigmentation. The colour shaded to a deep red in the posterior parts of the lung. A rudimentary fissure between the upper and middle lobes was present. No other fissures could be distinguished.

The lung was soft and doughy in consistency, except in the region of the cardiophrenic angle where it was quite firm and inelastic. Except in this place, the lung was crepitant throughout. The part of the lung served by the lower bronchial branch was small and of irregularly firm consistency, being firmest at the cardio-

phic angle. The main bronchus of this contracted part of the lung was completely occluded by a mass of firm whitish tissue. This mass was firmly attached to the wall of the bronchus in an area equal to about one-quarter of the surface of the mass, and at the point of attachment appeared to invade the wall of the bronchus but not to penetrate it. The remainder of the surface of the mass was free in the bronchus and covered by a glistening fibrous membrane. The mass was roughly mushroom shape, and measured about 5 cm. in diameter at the large end and was contained completely within the bronchus. The large end of the mass lay distally. The containing bronchus narrowed down beyond it to a little more than normal size. The stem of the mass pointed proximally and was unattached. It extended up the bronchus to its juncture with the bronchus of the upper lobe. The cut surface of the mass was creamy white in colour and uniform in appearance, except for an area of hæmorrhage in the large end of the tumour, measuring about one to two cm. in diameter. This area of hæmorrhage led to the surface of the mass at a small point buried in the crevice where the mass was attached to the bronchial wall. Large blood-vessels ran in close proximity to the tumour, but none appeared to be invaded. The bronchus containing the tumour bifurcated distally to it and each branch led to a bronchiectatic dilatation. The larger of these measured about 1.5 cm. in diameter and was full of lipiodol. The smaller measured about 1 cm. in diameter and was full of creamy yellow pus. No other bronchiectatic cavities were present and there was no blood in these cavities. The lung-tissue surrounding these cavities was firm, fibrous and mottled with grayish black anthracotic pigmentation. Clotted blood was present in the bronchus about the tumour. The cut surface of the remainder of the lung was dark pinkish red in colour with widespread blotching of darker red. The peribronchial lymph glands were soft, gray in colour, small, and showed no gross evidence of metastases.

All parts of the body, except the head were examined as carefully as the lungs, and no other significant pathological lesion was found.

Histologically the tumour was made up of cells which closely resembled those of the normal bronchial mucosa. They tended to be cylindrical in shape and to form rows or circular gland-like

structures. The nuclei for the most part stained darkly. The tumour cells invaded the wall of the bronchus in cords and masses, and extended a short distance into the fibrosed lung parenchyma beyond the bronchus. There was a delicate fibrous connective-tissue stroma with numerous capillary blood vessels. (See Fig. 1)

FIG. 1.—Carcinoma of the lung. The section shows the marked tendency to an orderly arrangement of the tumour cells.

DISCUSSION

About 400 other reported cases were looked over and in no other case was the duration so long as in the present one. Two cases of four years' duration have been reported, one by Adler¹ and the other by Kerley.² A case with a somewhat similar history was reported at the Laennec Society meeting in Toronto in April, 1928, the first hæmorrhage being seven years before death, and the autopsy revealing a carcinomatosis of the lungs.

The absence of metastases is noteworthy in a case of such duration as this one. Metastases were absent in 33 of Adler's 374 cases. The microscopical and gross appearance of the tumour also suggested its relatively benign character.

The presence of spontaneous pneumothorax might be explained by the rupture of an emphysematous bulla of the right lung, similar to that described in the autopsy report. Such an event might be brought about by increase in negative pressure in the chest when portions of either lung become atelectatic owing to aspirated blood obstructing a bronchus.

The presence of bronchiectasis was probably secondary to obstruction of the bronchus by the tumour. Such an event is known to be a common sequel of foreign-body obstruction of a bronchus.

The afebrile character of the illness was a strong diagnostic point.

CASE 2

F. D., a white male, aged 42 years. This patient's history dated back only four months before death. The illness consisted of persistent cough and sputum with increasing weakness and loss of weight. His temperature was normal for the most part but showed occasional periods of febrile activity. He had very large serosanguineous pleural and pericardial effusions.

Autopsy—Examination revealed a carcinomatosis of the left lung, with metastases in the neighbouring glands, parietal pericardium liver, lymph-nodes at the lesser curvature of the stomach, and the right adrenal gland. Healed tuberculosis of the peribronchial glands was found on the right side, and an old pleuritis was present on the right side with areas of calcification. A complete autopsy was performed without the discovery of other significant lesions.

Microscopical examination of the tumour showed it to consist of atypical epithelial cells without any tendency to orderly arrangement. The nuclei varied greatly in size, shape, staining quality and showed numerous mitotic figures. This growth is thought to be alveolo-

genic in contrast to the bronchogenic origin in the first case (See Fig 2).

A CASE OF ANURIA DUE TO DIFFUSE INFARCTION OF THE RENAL CORTEX*

By W. DE M. SCRIVER, B.A., M.D.,

Montreal

A. B., a French-Canadian woman of thirty-four years of age, was admitted on September 21, 1928, to the Royal Victoria Montreal Maternity Hospital with the typical history and physical findings of retroplacental hæmorrhage.

Due to the patient's poor memory there was difficulty in elucidating a full history of past illnesses. She stated that she had suffered from pains in the joints some years previously, but had otherwise been quite well. In 1913 she was married and since then had had twelve normal, full-term pregnancies. In November, 1926, there was an abortion in the third month of gestation, and again in September, 1927, in the sixth month. During the past three years the patient had voided somewhat less frequently than had been her habit, approximately three to four times daily, and occasionally once at night. She stated that micturition had continued thus up to the time of admission to the hospital. There had never been any œdema, but in this pregnancy she had suffered from flashes of light before the eyes, and attacks of dizziness. She had no knowledge of any pre-existing hypertension.

CLINICAL HISTORY

The present attack commenced suddenly, the day before admission, with sharp pains in the lower abdomen which persisted, the abdomen became rigid and there was a very small hæmorrhage *per vaginam*.

Shortly after admission to the hospital the membranes were ruptured artificially, followed an hour later by the spontaneous delivery of a six months' fetus. About 1000 c.c. of clotted

FIG. 2—Carcinoma of the lung. Cancer cells are seen in the alveoli.

* From the Department of Medicine, McGill University Clinic, Royal Victoria Hospital, Montreal.

Read before the Montreal Medico-Chirurgical Society, October 26, 1928.

blood were expelled with the placenta, the surface of which showed many white infarcts

The urine obtained by catheterization on admission showed a large amount of albumen, a few granular casts were noted, together with occasional pus cells and red blood cells, which were thought to be due to trauma in catheterizing. The blood pressure at this time was 170 (systolic) and 110 (diastolic). Seven hours after delivery 25 c.c. of urine were voided, a similar amount was obtained by catheterization five hours later, and only 10 c.c. after twelve hours, a total of 60 c.c. in twenty-four hours. All of these specimens showed a large amount of albumen and a moderate number of granular casts, but no red blood cells were seen.

At this stage the nephritis service of the medical department was called in consultation, when the following physical findings were noted. The patient appeared rational and relatively bright. There was no dyspnoea and no oedema. Pallor was well marked. The teeth were in poor condition, the nose and throat were negative. The pulse was regular, the radial vessels apparently a little thickened, the blood pressure was 160 (systolic) and 110 (diastolic). The heart was enlarged slightly to the left, no murmur was made out. The lungs were clear. The liver was not enlarged. The abdomen presented the usual post-partum features. Reflexes were active and no pathological signs were elicited. The fundi showed no hæmorrhage or exudate. An examination was made by the department of ophthalmology who reported: "A small, pigmented dot at the end of a small capillary close to the macular area of the right eye. There is also a patch of atrophied retinal tissue somewhat below this spot. This may possibly be, if anything, the evidence of an older acute outbreak of retinitis, it does not represent anything that has taken place at the present moment." The blood chemistry determined at this time showed a moderate urea retention of 0.528 grams per litre, with a more significant creatinine figure of 2.47 mgm per 100 c.c.

In spite of various therapeutic measures, including modified hot packs by means of the electric heater, hot colonic and bladder lavages, intravenous injections of 20 per cent glucose saline solutions, and dry cupping, no diuresis could be induced, a total of 11 c.c. of urine being

secreted on the following day and less than 1 c.c. on the third day. These specimens showed the same chemical and microscopic findings as the previous ones. Complete anuria then followed until the death of the patient on September 30th, nine days after admission.

As it was considered advisable to rule out the possibility of a surgical obstruction, on September 28th a cystoscopy was performed by the urological department in which no marked lesion was found in the bladder and the ureters were easily catheterized as far as the renal pelvis.

Most noticeable in the progress of the condition was the relatively clear mentality of the patient up to the time of her death. In spite of a steadily increasing nitrogen retention with a blood creatinine figure two days before death of 6.66 mgm per 100 c.c., none of the usual uræmic symptoms was noted, while the blood pressure fell steadily from 170 (systolic) and 110 (diastolic) on admission to 135 (systolic) and 85 (diastolic) two days before death.

A second interesting feature was the large output of fluid by the bowel, which ranged from 1,600 to 2,500 c.c. for the twenty-four hour periods, during which the patient was receiving a total of 4,000 c.c. of fluids. This elimination was aided by the administration of one ounce of magnesium sulphate three times daily, it is possible that this may explain why no oedema developed.

AUTOPSY FINDINGS

At autopsy there was no evident oedema, the peritoneal cavity contained about 700 c.c., and the pericardial cavity 40 c.c., of straw-coloured fluid, the pleural cavities, however, were dry. The uterus showed the usual post-partum condition and its vessels were intact. In the heart, which weighed 380 gm., no gross lesions were evident, microscopical section showed a moderate fatty degeneration of the musculature. There were a few small early atheromatous plaques in the aorta, and all the blood vessels appeared to be well preserved. The mucosa of the cæcum and transverse colon was dark red, swollen, oedematous, and riddled with numerous small irregular ulcerations.

Both kidneys were large, weighing 380 gm. each. The capsule was slightly adherent, and when stripped left a bulging surface, pale yellow in colour, with irregular, finely-mottled,

reddish areas. On section, the cortex, which measured 6 mm in width, was pale yellow and greasy in appearance, the differentiation between it and the darker reddish and apparently well preserved medulla being much accentuated. Between cortex and medulla was a narrow zone, bright red in colour. The vessels were engorged, pelvis and ureters were intact.

capillaries. In some areas which were better preserved there was an exudate of leucocytes and red blood cells, with hyaline casts in the tubules and patchy areas of calcareous degeneration. Directly under the capsule was a narrow band of relatively well preserved cortex. The cells of the medulla showed no marked lesions, the straight tubules containing scattered hyaline casts.

FIG 1—($\times 10$) Photograph of a small area from a complete longitudinal section of the kidney, eosin hematoxylin stain. Numerous infarcted glomeruli can be seen as small dots. In many cases their connection with the infarcted vessels is easily to be made out. The area of hyperaemia and extravasation in the cortex adjoining the medulla is well shown.

FIG 2—Higher power view of the cortex. Note the necrosis of the tubules, many of which contain hyaline casts. In the upper half of the field a thrombosed artery is seen, while at 5 o'clock is a glomerulus, the afferent artery of which is filled with thrombus.

and clear. Microscopical sections showed that the appearance of the cortex was due to massive infarction, with simple necrosis of the parenchymatous cells, the blood vessels being dilated and filled with blood and organizing thrombus, this condition extending into the

The etiology of this remarkable condition is being made the subject of a study by Professor Horst Oertel, who will make a further report on a pathological basis. My thanks are due to him for permission to use the autopsy records in preparing this case report.

Anti-Diphtheritic Immunization at the Maritime Hospital of Berck—Drs M and G. A. Mozer and Cofino give the results of the immunization of the children in this hospital during the past three years. During this period there were admitted 1,100 children afflicted with external forms of tuberculosis and rickets. During the three years previous to the institution of this procedure (December, 1925) there were 137 cases of diphtheria, of whom 12 died. Subsequent to this date

there were only 36 cases, 16 of whom were among the non vaccinated, with one death, and 11 in children who had received only two doses of antitoxin. They found after three injections of anatoxin that the proportion of positive Schick tests fell from 36 to 4.5 per cent. A fourth supplementary injection reduced to 4 the number of 44 patients in whom the Schick test had remained positive.—*Le Progrès Médical*, 1928, *clin*, 1757.

Editorial

THE MONTREAL HEALTH SURVEY

THE Montreal Health Survey, in view of the many interesting features it presents, stands as a demonstration of the necessity of making such surveys before planning any concrete, rational program of health work. Facts are thus brought to the surface, eloquent figures are found, and a full analysis of the situation is made possible. Public attention is then focussed on the recommendations presented, based on the survey, with the best prospects for their realization. Therefore, anyone interested in promoting public health in any community cannot but congratulate the Montreal Anti-Tuberculosis and General Health League upon the presentation of such a complete survey of health conditions in Montreal.

The time is now opportune to analyse the conditions necessary for the carrying out of the program laid out for improving existing conditions. As these conditions apply practically to every community their brief presentation in the *Canadian Medical Association Journal* seems to be advisable.

The first of these conditions is *the hearty co-operation of the medical profession*. Medical men are the natural advisors of the laity on health matters. Their routine daily contact with the sick draws their attention continually to the problem of prevention. So many are the evils encountered which could, and therefore, ought to, have been eliminated if proper measures had been resorted to in time! Contagious diseases, acute infections, industrial and other accidents, are illustrative examples. In their prevention members of the medical profession have then share. They must notify the proper authorities of all contagious cases they meet in their practice. They must help in every way in isolating these patients, in protecting contacts, particularly in excluding from school children living in the same home. They must give all possible information helpful in the carrying out of the epidemiological survey. They must also advocate and practise as much as possible vac-

ination against those diseases which can be so prevented, particularly small-pox, diphtheria and typhoid fever. They must keep themselves informed on the progress accomplished along these lines by scientists, notably in the case of scarlet fever and tuberculosis. With such help unreservedly given by the medical profession one can easily realize how much greater protection can be afforded our population.

A second condition essential to the success of any health program is *the qualification of the personnel taking part in its realization*. It is now known, and it must be accepted by all concerned, that public health is a specialty in the immense field of medicine. No one to-day can adequately cover all the subjects included in the medical sciences. Dr. George Vincent, President of the Rockefeller Foundation, in his annual report for 1923, has rightly pointed out this need in the following terms:

"The Rockefeller Foundation fixes its attention upon permanent, constructive activities in the fields of public health, medical education, and the premedical sciences. Experience clearly shows that the fundamental need in the progress of preventive medicine is a specialized personnel, thoroughly grounded in the underlying sciences and familiar with the best methods of practical application and administration. The idea that an ordinary medical education fits a doctor to be a health officer is a serious error which does much harm. He needs additional graduate training for what is recognized as a special profession."

This statement from so high an authority implies a twofold conclusion—that our universities give the necessary training, and that our health agencies, official and voluntary, make this training a *sine qua non* for the appointment of their personnel, medical, nursing, etc.

A third condition necessary in health protection extended to the community is *the development of the voluntary health agencies*.

These organizations, enjoying more freedom, can undertake special investigations, and can adopt particular activities more easily than the official departments. They possess also the additional advantage of being free from political interference. We are provided already with these agencies and their contribution to public health is a very valuable one. Their aim is to carry on their program harmoniously and side by side with the official health departments.

A fourth essential condition in the success of any project in health matters is *public support*. This implies the absolute necessity of health education. For its achievement all must participate, our school and university authorities as well as the medical profession. The teaching and the practice of hygiene in our elementary schools could well be further developed with great advantage. At the

University of Montreal, lectures on hygiene are given to the students of all the faculties and affiliated schools. The aim is to prepare the leaders of to-morrow to better understand and carry on their responsibilities, when in office as members of school commissions, municipal councils, or in the provincial legislature. The medical profession has also the duty of co-operating in the educational movement of the population in health matters. Naturally, all look to the medical profession for guidance in these questions.

Let us hope that, with all these conditions fulfilled, and others which might be added, the health survey of Montreal will be helpful not only to the city proper but also to all the municipalities of the country. It is our duty to aid in extending its benefits to all of our countrymen.

J. A. BAUDOUIN

THE PRESENT STATUS OF THE ANTIRACHITIC VITAMIN PROBLEM

A FEW years ago those interested in the newer therapy of rickets were much puzzled by the fact that this disorder could be cured by two such different agencies as ultra-violet light and cod liver oil (through its content of vitamin D). The matter was considerably clarified when it was discovered that radiation of the food in experimental rickets in rats also afforded protection, and another step forward was taken when it was found that radiated cholesterol added to a rachitic diet also conferred immunity toward rickets. Since cholesterol is a ubiquitous substance so far as living cells are concerned, it was easy to bring the phenomena of light action and cholesterol action together by assuming that light *per se* was effective because of its activating action upon the cholesterol in the skin.

It then became a matter of interest to discover the nature of the action of light upon cholesterol which gave the latter its antirachitic property. It seemed a foregone conclusion that cholesterol must be the parent substance (the provitamin) of vitamin D, since those investigating the problem had been careful to obtain cholesterol of presumably absolute purity. It seemed as though ultra-violet light must either produce

some obscure change in the cholesterol itself or cause some active substance to be formed from it. It was even conceivable, in a vague kind of way, that a portion of the energy of the light used might be stored by cholesterol, later to be given up to the animal and to produce the antirachitic effect.

Finally, however, it was discovered that not every sample of cholesterol could be converted into an antirachitic agent by ultra-violet light. When cholesterol, for example, was first converted into a chemical derivative, cholesterol dibromide, which was then changed back to cholesterol, the substance so obtained, though identical so far as a chemist could determine with the original substance, was no longer activatable by light. Other methods of treating cholesterol also led to the formation of products which could not be activated. It was natural, therefore, that the view should appear that perhaps the cholesterol which had first been used was not as pure so had been believed, that possibly the active agent might be a contaminating substance so similar to cholesterol that in the processes of purification it was not eliminated. Rosenheim and Webster, of the National Institute for Medical Research in London, became convinced of this

through their experience with cholesterol purified by the dibromide method mentioned and called the hypothetical provitamin "vitasterol." They communicated their experience to Windaus in Göttingen, who had become interested in the problem through Hess of New York, who, simultaneously with, but independently of, Steenbock of Wisconsin, had discovered the activating effect of light upon various foodstuffs. Windaus, to whom much of what is known concerning the chemistry of sterols (to which group of chemical substances cholesterol belongs) is due, suggested that a sterol called ergosterol might be the real provitamin of rickets, the vitamin itself being formed from it by the action of ultra-violet light.

When this view was put to the test by Hess and Windaus, Rosenheim and Webster, and since by many others, it was found that ergosterol when radiated did actually confer immunity to rickets and cured rickets already developed. At the present time, therefore, it is current opinion among those working at the problem that ergosterol is the provitamin of rickets. Investigation of a number of compounds closely allied to ergosterol has proved them to be non-activatable, hence the view appears justified that ergosterol is the specific parent substance of vitamin D.

The sterols fundamentally are alcohols, but their relation to ordinary alcohol is exceedingly slight. The molecule is much more complex than that of ethyl alcohol. A complete formula for ergosterol cannot be written at present. It is what the chemist calls an unsaturated compound, there being double bonds between some of the carbon atoms which make it a rather reactive compound. One of its most useful attributes is the fact that when ultra-violet light is passed through

a solution of it some of the rays are absorbed, forming so-called "absorption" bands. These are quite characteristic and there is reason to believe that it may be easier to determine the vitamin D content of foodstuffs by means of the spectroscope than by experiments with animals or by a chemical method for the determination of ergosterol.

The nature of the change produced in ergosterol by ultra-violet light which converts it into the actual vitamin is at present wholly unknown. Likewise, the action of the vitamin in the body is largely unknown though it has been suggested by Hess that its action may be indirect, through stimulation of the parathyroid glands, thus raising the calcium content of the blood, which is low in rickets. That irradiated ergosterol does raise the calcium content of the blood, there is no doubt, and that it may do so through a mechanism involving the parathyroids is conceivable.

It was at first believed that there was no danger in administering an excess of vitamin D, but recently this view has been questioned. Following very high dosage excessive laying down of calcium in some tissues has been reported and Hess states that in children fever and a peculiar state of drowsiness have been observed occasionally. It is suggested by Hess that 0.5 mg. of ergosterol be used as a prophylactic and 1.0 mg. for the average case of rickets, both being daily doses. These are equivalent to about 7 and 14 teaspoonfuls of a good preparation of cod liver oil. Ergosterol is therefore about 15,000 times as efficient as cod liver oil.

Ergosterol, probably through its effect on the level of blood calcium, is quite as effective in tetany (including tetany in adults) as in rickets, and favourable results have been reported in osteomalacia.

R. L. STEINLE

AVERTIN ANÆSTHESIA

SINCE the spring of 1927 numerous papers and references have appeared in the German medical literature concerning a new general anæsthetic, at first called E 107 and later "Avertin." It is a product of the pharmacological division of the dyestuff industry, has been supplied for trial to a

number of hospitals, but thus far has not been released for general use.

Chemically avertin is tribromomethyl alcohol ($\text{CBr}_3\text{CH}_2\text{OH}$), a crystalline compound soluble in water to the extent of 3.5%, the solution undergoing decomposition when heated to 60° . It is detoxicated rapidly in

the liver by conjugation with glycuronic acid (1166 gm have been given in seven days in a case of tetany, successfully treated, without noticeable damage) Injury to the liver and kidneys seems to be practically nil

Avertin is administered rectally in aqueous solution Sleep ensues usually in from three to ten minutes without the appearance of any unpleasant symptoms and lasts for about two hours, being then followed by what is referred to as an after-sleep lasting for several hours On awaking there are no unpleasant recollections, and postoperative vomiting, headache, and salivation are practically absent Patients who have been subjected to both ether anæsthesia and avertin anæsthesia have had no hesitation in stating preference for the latter However, the opinions of surgeons have not been unanimous in favour of avertin A number of deaths have been attributed to its use and rather numerous cases of alarming circulatory and respiratory depression have been reported

When the fact is taken into consideration that the early use of avertin was necessarily of an orientating character it would appear that these early unfortunate experiences should not be allowed to weigh too heavily against it Indeed a change of view has taken place with regard to its probable field of usefulness, and it may be that, while avertin will doubtless not turn out to be a complete substitute for ether, it may find a more modest but still useful place among anæsthetics In the beginning the attempt was made to use avertin alone and in all cases as the sole anæsthetic agent It was soon found, naturally, that the same dosage (on the basis of body weight) was not always equally effective, that the higher doses (up to 0.2 gm per kilo), often necessary to produce complete muscular relaxation, sometimes produced serious falls in blood pressure and occasionally temporary cessation of respiration By using smaller doses it was observed that, while complete surgical anæsthesia was obtained only part of the time (in approximately 50 per cent of the cases), the amount of ether required as a supplementary anæsthetic was often so small that the recovery period resembled that of a good case of avertin anæsthesia rather than that of ether anæsthesia Of course when the quantity of ether used was large its post-operative

actions became evident The procedure of starting with a small dose of avertin and then administering additional amounts to produce surgical anæsthesia has not found favour At present 0.1 gm of avertin per kilo is not exceeded by numerous surgeons, some ether then being necessary in many instances

In the beginning, in addition to deaths from circulatory and respiratory depression, several deaths also occurred from local intestinal damage This appears to have been due to the use of solutions heated to too high a temperature in their preparation, the dibromacetaldehyde formed being injurious locally Since this danger has been known and avoided practically no intestinal damage has been noted Other ill effects which a few surgeons have attributed to avertin have been post-operative excitement and increased bleeding, but these opinions do not seem to be shared by the great majority of those who have used it

Theoretically, avertin may be objected to on the score that once given its action cannot be recalled This argument loses its force somewhat if the substance is used as above mentioned—in minimal dosage with ether as a supplement

The long recovery period has been regarded by some as an advantage and by others as a disadvantage The depression of post-operative pain may cause it to be regarded in the former light On the other hand the patient requires considerable post-operative watching because of the possibility of breathing being interfered with by falling back of the tongue

Obstetricians seem to be divided on the question of the applicability of avertin in parturition Some find the position of the fetus to interfere with its administration, and others state that the solution is frequently ejected during the contractions Just when to give it also constitutes something of a problem

A few papers have appeared concerning the use of avertin in psychiatry The observations have been quite favourable Quick sleep is said to ensue in the most violent cases

In the case of hyperthyroidism the opinions are conflicting Some describe their experience in most favourable terms, others seem to have been less fortunate R L STEHLE

REFLECTIONS ON MEDICAL WRITING

IT is the privilege of a retiring President to employ considerable latitude in choosing the subject for his final address. Dr W B Howell has exercised this privilege freely—and delightfully—in the address we publish in this number of the *Journal*. His “reflections” are those of a specialist, it is true, but they are refreshingly free from the usually, though not at all necessarily, narrowing influence of specialization. Instead, we have the outlook of one who is not only keenly alive to the real importance of the apparently trivial and frequently neglected details which accompany the giving of anæsthetics, but who also shows himself to be appreciative of matters quite remote from the subject of anæsthesia.

We cordially endorse his comments on the carelessness of expression which is so frequently evident in medical writings of the day. It is quite true that very few possess the gift of writing attractively, but how much less unattractive might a great portion of medical writing be made—to say nothing of how much less would be printed—if more pains were taken to use clear and exact English. The more one sees of medical writing the more surprised one is at the incoherence of the average writer, and also at the discrepancy between the excellence of his actual work and the confused expression of his thoughts. How can we avoid the conclusion that the thinking itself is confused?

One feels also that writing is often bald and uninviting because the writer does not really believe that it matters very much about the choice and arrangement of his words if they convey something of his meaning; he is content. How difficult is the task they are sometimes given to perform!

It would be easy to add to the illustrative examples so aptly given by Dr Howell. Take the following sentence which appeared in a recent number of a leading medical journal, “This disease (tularaemia) stands unique as the first truly American disease, and the guiding spirit that has made the accomplishment possible is Dr Blank.” Could we blame a disinterested reader of this statement for thinking that Dr Blank had brought about this disease himself? Or, take this sentence from a paper on a surgical case: “In view of her improvement a posterior gastroenterostomy was done.” The disinterested reader again might conclude that the woman would have done better *not* to improve.

On no point are we in more heartfelt agreement with Dr Howell than on the gross distortion of the word “pathology” to its indefensibly slipshod use as a synonym for disease itself. Where indeed shall we stop in the development of such inaccurate terminology? We are surprised that Dr Howell, in forecasting the changes in the Prayer Book which might be expected to result, did not suggest that the rhythmical beauty of the phrase “in sickness and in health” would probably be replaced by the cacophony of “in pathology and in physiology”!

This is a *reductio ad absurdum*, but if the would-be author persists in letting his sentences run loose he must not be surprised if they sometimes appear absurd to those who watch their antics. Still less should he be surprised at failing to make his meaning clear if he mutilates his language by a slothful indifference to the accepted meaning of its words.

H E M

A TERCENTENARY THOUGHT

THREE hundred years does not seem to be a long time in retrospect. It does not take us back to the discovery of America or even to the founding of Port Royal or Quebec. And, yet, less than three hundred years ago, men suffered under the thralldom of authority, ecclesiastical and other, to an

extent which can scarcely be realized today. It is now three hundred years since Harvey gave “*De Motu Cordis*” to the world. It was published after years of hesitation, after the main features had been expounded to physicians, medical students and scientists, and against the advice of Harvey’s best

friends There was much fear of offending dignitaries of Church and State Perhaps because of this, but more probably because of the promise of better sales, Harvey went to Frankfurt for a publisher It is unlikely that he chose a foreign publisher because of timidity We read that Harvey, who was court physician to Charles I, accompanied that monarch into the field of battle at Edgehill, that he became sated with the spectacle of battle, and while the fighting was most severe he sought out the shade of a hedge where he promptly became engrossed in the reading of a work on "Generation" A man who could sit quietly reading while a furious battle was being waged about him was unlikely to have much fear for personal safety There is some reason for the belief, moreover, that the caution which Harvey showed was due to reasons of state, for he was an intimate of the Court, rather than to fear of personal suffering as a result of publishing a work which opposed all the current teaching about the function of the heart and blood vessels

The publication of the book created a storm, and Harvey was vigorously denounced in all quarters Gradually, however, there came a realization of the reasonableness and importance of his teaching, but, while he gained many adherents, it was not until after his death that Malpighi could demonstrate microscopically that Harvey had really contended for the truth

"De Motu Cordis" was published in 1628 In the three hundred years which have elapsed, a great change has come over mankind No book of such momentous importance has since been published Today, of the making of many books there is no end There is no fear that the presentation of novel views will create hostility of either Church or State We are very free, but are we much better off? It is possible that earlier publication of "De Motu Cordis" might have proved beneficial to mankind On the other hand, it is probable that it would be of general advantage if many of the books being published to-day were withheld from some years for deliberation and for the amendment which such deliberation would likely bring about Few have the patience of Mortgagn, who waited until he was well advanced in years before giving his great work to the world It is just possible that keener scrutiny and franker criticism of new books would have a restraining influence upon our impetuous authors. As it is, we really suffer from lack of restraint, and while we scarcely wish a return to the conditions of Harvey's day, we might be the better for some control Certain it is that the freedom we profess to enjoy requires each of us, in the course of his reading, to winnow out much chaff, and to be content with less than the expected amount of wheat If the present tendency persists, what will the outcome be?

W H. HATTIE

OUR FATHERS

The Roman gather'd in a stately urn
The dust he honour'd—while the sacred fire,
Nourish'd by vestal hands, was made to burn
From age to age If fitly you'd aspire,
Honour the Dead, and let the sounding lyre
Recount their virtues in your festal hours,
Gather their ashes, higher and still higher
Nourish the patriot flame that history dowers,
And, o'er the old men's graves go strew your
choicest flowers

SOMETHING of the spirit voiced in a poem by the great Nova Scotia statesman, Joseph Howe, of which the above is the concluding verse, led the medical profession of the Bluenose province to a notable celebration during the week of October 15th The occasion was the seventy-fifth annual meeting of the Medical Society of Nova

Scotia, when a number of medical events were very happily combined, including the diamond jubilee of the Dalhousie Medical Faculty Naturally, such events created an atmosphere of retrospection, and men reminded themselves and one another of the worthies of other days, who were pioneers in the Society and in the Medical School Some of the difficulties which had to be overcome were spoken of, but how can we of this day estimate the courage, the faith, and the perseverance needed to win through in the pioneering times!

Perhaps, because of unwillingness to admit inferiority, we sometimes endeavour to comfort ourselves by professing that life was

never before so complicated or so difficult as at the present time. We almost envy the serenity of the age when science moved but slowly, slowly, in contrast to the mad haste with which it now bounds from place to place, inciting us to furious effort to keep the moss off our backs. Even though our forebears moved in a cucle ("with much iteration and small progress," according to Francis Bacon) just as we do, we like to feel that their pace was slower than ours and therefore less conducive to dizziness. If there is some uncertainty about this, we can assert positively that never before the birth of this century were the nerves of medical men flayed by the flaunting of pictures of rats fed on devitaminized diets. Our forebears were spared such horrors, didn't even dream of vitamins, and had no worries about calories. When they used the lancet (*magnum donum Dei*, as it was termed by Rush) it was seemingly with a delightfully cheerful abandon, they gave little thought to transfusion, and the "matching" of blood did not concern them in the least. Nor did they have to face the bewildering problem of how to vaccinate a gul where it would not show. Because of such things, we say they lived the simple life, and fancy ourselves to be much more "put to."

The early meetings of the Medical Society of Nova Scotia are recorded in singularly legible hand-writing which really looks like copper-plate. Many of the s's bear a striking resemblance to our f's, otherwise there is nothing to suggest that the physicians of seventy-five years ago were not men of like passions to us. They had no inkling of the

enormous studies which were to be made in three-quarters of a century, but they were zealous to improve the status of the profession and to increase its usefulness to humanity. And the story of the beginnings of the medical school at Halifax is one of heroic struggle and sacrifice such as could be maintained only by men of enduring faith and almost prophetic vision. It is well that we should look back over the records of these early days and of the men who laid the foundation of a structure in the building of which we are privileged to share. Some of our smugness departs from us as we learn of the difficulties the "old men" had to overcome, of their high sense of professional honour, and of the sheer determination with which they faced a future of which they could hardly feel confident. Because of the trials and struggles and triumphs of these men we have a goodly heritage—the lines have fallen to us in pleasant places. When we recount their virtues we merely acknowledge a debt we cannot pay. Surely the least that we can demand of ourselves is to fitly aspire and honour the dead by reverently cherishing their memories, and to keep the torch they transmitted to us alight and aloft until we must pass it on to our successors. This sentiment evidently played a part in determining the program for the Bluenose celebration, which provided not merely thought upon the past but instruction and inspiration for the future. The celebration was admirably conceived and carried out in a way which won the unstinted plaudits of those in attendance.

Editorial Comments

CANADIAN PUBLIC HEALTH ASSOCIATION, SEVENTEENTH ANNUAL MEETING

The Canadian Public Health Association held its annual meeting during the week of October 8th, in the city of Winnipeg. This Association is an organization largely made up of those specifically engaged in the field of preventive medicine. With the exception of one meeting of the Section of Public Health Nursing, and one meeting held by the Section of Laboratory Workers, the sessions were of a general character, and the subjects presented for consideration, while covering every phase of public health

activity, were of sufficient general interest to demand the serious discussion of those in attendance. Particularly true was this in the case of the report of the Committee on Regulations governing Communicable Disease Control and the symposium on County Health Units. There seemed to be no conflict of opinion among those present as to the early necessity of a change in our method of public health organization as it applies to rural and small urban communities, and there existed an equal measure of dissatisfaction with the measures set aside in some of the provinces for dealing with certain of the minor communicable diseases.

The meeting, which was probably the most representative one held by the Association in recent years, brought together members of the Association from seven of the nine provinces in the Dominion, and with almost one-half of the registration being from outside the Province of Manitoba, was deemed to be sufficient evidence of the continued usefulness of the Association to warrant the purchase of the present organ of the Association, namely, *The Public Health Journal*, which, commencing January 1, 1929, will be edited and published by the Association itself.

Both the city of Winnipeg and the Province of Manitoba evidenced their interest in the Association by their hospitality, and the members carried away from the meeting not only much that was of profit but recollections that were pleasant in the extreme. Much of the credit for the success of the convention was due to the efforts of the local Committee on Arrangements, which was headed by The Honorable W. E. Montgomery and Dr. Douglas.

J. T. PHAIP

ANNUAL REPORT OF DEPARTMENT OF PUBLIC HEALTH OF NOVA SCOTIA*

Some interesting facts are to be found in the recently issued report of Dr. A. C. Jost, late Provincial Health Officer for Nova Scotia. The general death rate is 11.9 per 1,000 which is one of the lowest recorded for the province, and the tuberculosis death rate has fallen below that for the previous year. On the other hand the infant mortality has been higher than in past years, due largely to conditions in the mining areas. There is very wide variation between the rate in the mining town of Glace Bay, for example, where it is 195.6 and the agricultural town of Menton where it is 36.3. The report shows clearly how the rates are to be accounted for.

As regards the birth rate, Dr. Jost makes the following comment:

"A feature quite noticeable in the records of the province is the evidence that it is participating in the very widely experienced reduction of the birth rate, which has caused comment almost wherever records are being kept. With each year since 1921-22 there has been a reduction in the number of births taking place in the province, so that during the year the number of reported births was smaller than had been reported for many years."

* *Public Health Journal*, 1928, xix, 282

Another point brought out by Dr. Jost is the alteration in the ages of the mothers. Most of the decreases in births (about 85 per cent of the total decline) has been amongst mothers up to the age of thirty, there is now a higher percentage of births amongst mothers aged 31 and over. No attempt is made to explain these variations, and it is stated that similar changes have been noted in other places. There can be little doubt that modern industrial and social conditions are partly responsible for marriages taking place somewhat later in life, and to some extent in delaying the bearing of children.

But social conditions are not the only factors which influence variations in a country's birth rate. In the discussion at the British Medical Association's meeting this year, on the subject of "The falling birth rate," it was shown that from a biologist's point of view a decline in the birth rate was something that was expected to occur in the natural course of things, in all populations†. In Dr. Crew's words, "To the biologist a falling birth rate is nothing but the sign of the approaching end, not of a people or of a culture, but merely of a population growth-cycle."

THE JOURNAL OF THE COLLEGE OF SURGEONS OF AUSTRALASIA

The College of Surgeons of Australia has published the first number of the journal which is to record their activities. It is intended also, however, to make this journal the medium for publishing original papers which will reflect the progress of surgery in Australasia. We note with interest in the present number articles on the development of similar colleges in England, Ireland and the United States.

We extend our congratulations to the editorial board of this publication and our best wishes for its success. The first number has set a high standard of excellence, both in material and in general appearance and if this standard be kept up the success of the venture is assured.

H. E. M.

We regret to hear, as we go to press, of the severe illness of Prof. Oskar Klotz, of Toronto, on his way home from Africa. We are glad to learn that the worst is past. His recovery, however, it is said, will be slow.

THE RECENT TRIP OF THE CANADIAN TUBERCULOSIS ASSOCIATION REPRESENTATIVES

By J H ELLIOTT, M D,

Toronto

On August 24th, a party of thirty-two physicians, members of the Canadian Tuberculosis Association, sailed from Montreal on the White Star *SS Regma*, to study various phases of antituberculosis work in Great Britain, France, Switzerland and Italy. The objectives were the Sixth Conference of The International Union against Tuberculosis, held at Rome September 24th to 27th and the Annual Meeting of The National Association for the Prevention of Tuberculosis, held in London, October 15th to 16th. An itinerary was arranged whereby the party was able to observe many and varied activities in the countries visited.

That such a large party from Canada should attend the congress was made possible through the action of the Sun Life Assurance Company of Canada, in placing at the disposal of the Canadian Tuberculosis Association thirty scholarships to be awarded to tuberculosis workers, selected from each of the provinces of the Dominion. The party included sanatorium physicians, directors of clinics, tuberculosis officers (diagnostic services) of various provincial government, and included the secretary and president of the association. With a few exceptions, the men were accompanied by their wives or other members of their families, making in all a group of nearly seventy travelling as a party.

From the day of their landing at Liverpool when they were first the guests of the Dean and Chapter of the Cathedral, and, then, luncheon guests of the Corporation at the Liverpool Open Air Hospital, until eight weeks later, previous to re-embarking for Canada, when they were officially received by the Lord Provost and Corporation of the City of Glasgow in the Satinwood Room of the City Chambers, with the Under Secretary of State for Scotland present, the party were received and entertained with the utmost courtesy and kindness.

The itinerary, with over one thousand miles of motor trip, included Great Britain, France, Switzerland and Italy. The impressions of representative members indicate that the tour has been not only extremely interesting but most instructive. The attention of the medical members was directed to matters pertaining to

tuberculosis and to various public health aspects both in administration and practice.

Among the problems investigated were the following: municipal housing schemes, sanatorium construction and equipment, diagnostic and therapeutic measures, post-sanatorium care of the tuberculous, infant and child welfare, special measures and activities to protect children from infection, governmental and voluntary contributions to maintenance and construction programs, public health activities and administration, as exemplified in such cities as Birmingham, London, Paris, Nancy, Edinburgh and Glasgow. Great Britain's national tuberculosis scheme was outlined at the Ministry of Health, Whitehall, by Sir George Newman and Dr F J H Coutts. In France the national and departmental plans were presented by the Comité National de Défense Contre la Tuberculose. In Italy the national scheme with the outline of compulsory insurance against tuberculosis was presented to the International Conference in the reports of the Italian National Fascist Federation against Tuberculosis.

Officially received or entertained as guests of the Corporations of great cities, such as London, Liverpool, Birmingham, Glasgow, Orleans, Paris and the Department of the Seine, Nancy and the Department of Meurthe-Moselle, and by the Governor of Rome, every facility was offered for the study of all that related to the objects of the tour.

An important feature was a daily conference on the ship eastbound, with general and helpful discussion of such subjects as sanatorium construction and costs, sanatorium administration and costs, travelling clinics, tuberculosis in childhood, Calmette's vaccine, and tuberculosis progress in Canada. On the return voyage, in spite of tempestuous seas, opportunity was taken to crystallize opinions and observations made on the tour in relation to such subjects as government aid, national schemes, milk-borne tuberculosis, sanatorium construction, protection of the exposed child, treatment of non-pulmonary forms of tuberculosis, orthopaedic practice in bone and joint infections, natural and artificial heliotherapy, colonies and after care, clinical practice in pulmonary disease, including graduated exercise, sanocrysin, and occupational therapy.

Great Britain offered an interesting field for the observation of methods of treatment of the non-pulmonary forms of tuberculosis. For example, in Glasgow the death rate from pulmonary tuberculosis is 92 per 100,000 and from non-pulmonary, 36 per 100,000. This city has

under observation 4,900 non-pulmonary cases. It has 450 beds for non-pulmonary cases in hospitals and sanatoria and is building at Mearnskirk for 330 additional beds. Surgical operative interference in bone and joint tuberculosis is less frequently seen now than a few years ago. With the recognition in Canada, as elsewhere, that tuberculosis is a general disease and rarely local, more and more of such cases are referred to our Canadian sanatoria for general care and prolonged rest treatment. In arranging the tour this phase of orthopaedic treatment received special attention. Special clinics were arranged by the staffs of many institutions under such well known surgeons as Sir Henry Gauvain, at Alton and Hayling Island, Mr Girdlestone, at the Wingfield Orthopaedic Hospital, Oxford, Mr Jardine, at Edinburgh, Mr Watson, at Robroyston, Glasgow, T Hartley Martin at Leasowe, Liverpool, and Dr Rollier at Leysin. This highly specialized instruction was much appreciated, and with other lectures and demonstrations, such as that given by Sir St Clair Thomson on laryngeal tuberculosis, cannot but be reflected in practice in Canada.

It was noted with interest that a steadily increasing number of sanatoria are establishing workshops with various industries, on an economic wage, for patients able to do a part day's work but unable to compete in the general labour market. In connection with a few sanatoria these have grown into colonies or village industries where the patient or ex-patient is able to live with his family and be self-supporting. The scheme presents many difficulties. It has proved most successful where the patients are ex-service men who have a pension. This with their wages or earnings from part time work enables them to support a family in comfort, while working under conditions which lessen the probability of relapse.

In France no opportunity was lost to secure information as to the results of an extensive movement to prevent tuberculosis by the placing of contact children in tuberculosis-free homes, the method first devised by Grancher and modified by Léon Bernard and his co-workers. Visits to the clinics at the Laennec Hospital, a train trip to Orleans, and a motor trip of sixty kilometres through the countryside south of Orleans, gave the party a practical demonstration of the truth that prevention is better than cure. Whereas many of the children who remain in an infective environment die of tuberculosis, those who are removed for a period of four years show no deaths from this cause, and the mortality from all causes is greatly lessened.

Calmette's method of preventive vaccination of contact children was a subject of great interest. Clinical workers in France seem to have rather generally accepted his claims and his

evidence. In England the general verdict is "not proven." Petroff, of Saranac Lake, believes that the whole experiment must be gone over carefully before the results claimed can be accepted. We believe the League of Nations has drafted a basis of statistical inquiry, which, if followed over a sufficient period, will aid in arriving at a conclusion as to the efficacy of B.C.G.

The application of natural and artificial heliotherapy in the treatment of non-pulmonary and pulmonary tuberculosis was the subject of extensive inquiry. The Finsen lamp was found to be generally used, and successfully used, in lupus, a rare disease in Canada. In the use of natural and artificial heliotherapy the patient is also subjected to the effects of air exposure and it appears difficult to arrive at any basis of actual valuation of these two therapeutic agents. In Scotland, the air bath, with but little direct light exposure, appears to have given excellent results. Further experimentation and investigation appear necessary to settle some controversial points. Heliotherapy, natural or artificial, is capable of doing immense harm if improperly applied, and it seems fitting to issue a word of caution to the public as to the over-use, and indeed dangerous use, of such powerful agents as sunlight and various forms of artificial light treatment. One strict rule was found to be universal, that direct exposure to the sun is never to be used in febrile cases.

That Italy is wide awake to the importance of national action against tuberculosis is indicated by the fact that in addition to a definite public health program a yearly appropriation is made of 300,000,000 lire for tuberculosis work by the Mussolini government. His Excellency Benito Mussolini presided at the opening of the conference, and was also at the reception given by the President of the Fascist Federation against Tuberculosis, when a number of the delegates were presented. In addition to the three leading discussions, lectures were given by Prof Brauer on "The surgery of pulmonary tuberculosis," by Prof Morelli on "Foilanni and pneumothorax," by the Minister of National Economy on "Compulsory insurance against tuberculosis in Italy," and the Italian Department of Health projected a most interesting and instructive film, illustrating the active work of the department in industrial hygiene, municipal hygiene, and antituberculosis work in Italy. Canadian delegates were nominated to take part in discussions on the program and made excellent contributions in the short time allotted.

At the meeting of the National Association for the Prevention of Tuberculosis in London the Canadian contributions were of a very high character and reflected great credit upon Canadian medicine.

The members of the tour have returned with

a vast amount of valuable information, some of which, it is hoped, will be made available through the columns of the *Journal* to its readers. Some practical measures applicable to Canada and its provinces should be evolved from such a comprehensive plan of study and investigation as that undertaken by the Canadian Tuberculosis Association.

ACUTE CONDITIONS IN THE LOWER ABDOMEN OF THE FEMALE*†

By W. W. CHIPMAN, M.D., F.R.C.S. ED.,

*Professor of Gynaecology and Obstetrics,
McGill University, Montreal*

[This address is reprinted in full from the *British Medical Journal*, 1928, II, 475—ED.]

Two general considerations

1 The genital tract in the female is a hollow cylinder, bifurcate above, which communicates directly between the skin surface and the peritoneal cavity. A direct channel, or avenue of communication between a contaminated skin surface and this mesothelial space! (Victor Bonney)

And this genital tract is subject to many vicissitudes. There are the traumata of menstruation, of childbirth, and abortion, and the dangers associated with venereal disease. It is an imperfect world. Hence in the female the frequency of acute infections of the lower abdomen.

2 The peritoneal cavity is one of the three large enclosed chambers of the body—it is the largest of the three, the largest lymphatic space. Its absorptive surface is immense, compared either with the pleura or the subdural space. Hence the danger of an acute infection of this large space. The peritoneal cavity—an organismal Valhalla—a perfect incubation chamber.

These acute conditions are sometimes grouped together under the term, "The acute abdomen," "The emergency abdomen," or "The abdominal emergency." The point of the emergency concerns both the patient and the surgeon, and any given individual has only one abdomen. To open or not to open—that is the question, a decision oftentimes of very grave importance.

I need not tell you that the opening of the abdomen should never be lightly or carelessly undertaken. I object to the term of "giving the patient the benefit of an exploration." "Open and see" is a foolish behest. If too often done this may be interpreted as "condemning

the patient to an added injury." In surgery we must remember the three "C's"—caution, care, as well as cutting. You will also agree that before any abdominal operation is undertaken a vaginal examination, a rectal examination, or both, should invariably be made.

In general terms, these acute conditions may be grouped as follows:

- 1 Hæmorrhage, a concealed hæmorrhage
- 2 Acute infections, usually of the uterus, the Fallopian tubes, or the appendix
- 3 Perforation of the bowel or other hollow viscus—perforation or rupture
- 4 An acute bowel obstruction
- 5 Strangulation of any organ or neoplasm.
- 6 The passage of a ureteral stone
- 7 A uterine abortion, spasmodic dysmenorrhœa, or even a bladder retention

For the gynaecologist the most common of these are a ruptured ectopic pregnancy, an acute appendicitis or salpingitis, a uterine infection, strangulation, thrombosis, or an ovarian cyst, or uterine fibroid with a twisted pedicle.

Speaking in a general way for all these conditions, some of them are at once recognizable—he who runs may read—while others require a most painstaking differentiation.

May I first make two pleas of a preliminary character? The first concerns the wisdom of a careful case-history, for in many of these conditions the previous history, or the story of the onset, may afford the clue. Sir James Mackenzie pointed out that in difficult cases the diagnosis frequently depends more upon an exact history than even upon a careful examination. My second plea is always to pass a catheter, and to examine the resulting urine.

I shall now discuss in a general way the various signs and symptoms of these acute conditions.

Pain is always the outstanding symptom. It may well be defined as Nature's expostulation to an injury, and its function is a protective one. La Rochefoucauld has told us that pain is the greatest liar in the world, but it is wise not always to believe this. At times it is a liar, and so for the matter of that are all men, and a few women, but I believe it is wise to take the following advice: "Never open the abdomen for pain only"—for pain only and with no accompanying signs or symptoms.

The most important sign, perhaps, is the face—the abdominal face—the facial expression, and this never lies. So often it is the anxious peritoneal face, apprehensive. In hæmorrhage it is pallid, often waxy, and the muco-cutaneous line of the lip is unduly sharp and pronounced. There is the grey ashen face of shock, and the flushed or cyanotic face of a severe toxæmia. The severity of the lesion can often in this way be immediately inferred.

And there is the attitude of the patient, her decubitus and her mobility. If the lesion be

* A paper read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Cardiff, 1928.

† Reprinted from the *Brit M J*, 1928, II, 475.

acute and intraperitoneal, the patient lies invariably upon her back, and with her knees flexed. Any movement is a torture. On the other hand, if the patient moves readily, and turns easily on her side, there is no grave lesion within the abdomen. I have often found this test of asking the patient to turn over on her side of great service.

So far, you will observe, I have not mentioned either the temperature or the pulse rate. I shall refer to them later in their special place. Let us now consider the three commonest of these lower abdominal conditions. These are hæmorrhage, acute infections of the appendix or Fallopian tube, and a strangulation or thrombosis of a pelvic organ or neoplasm.

1 HÆMORRHAGE

The first of these is hæmorrhage. The common site, of course, is a ruptured tubal pregnancy. A severe hæmorrhage may arise, however, from other situations—for example, from a ruptured Graafian follicle. Three years ago Primrose of Toronto reported six such cases. I have met one in my own practice, and there was a large loss of blood. Again, a varicocele may rupture, and a uterus ruptured during labour, or perforated even by a sound or curette, may lead to a severe intraperitoneal hæmorrhage. The history here is all-important.

Usually the condition is that of ectopic pregnancy. As you know, the history of the pregnancy, the amenorrhœa, is often indefinite. Rupture occurs usually between the seventh and the twelfth week, and this rupture may be large or small. The dangerous situations are the isthmus and the cornu of the uterus. If large, the hæmorrhage is usually severe—the cataclysmic case with pallor, subnormal temperature, rapid and thready pulse, an-hunger, cold and clammy extremities. The abdomen is tumid and tender, frequently tympanitic, for the bowel floats, the blood has a high specific gravity. The pouch of Douglas may be full and depressed, and a feeling of crepitation may be present as the finger breaks the blood-clot. There is frequently the history of a dagger-like thrust of pain, with immediate faintness or collapse. A uterine trickle of blood is often manifest, together with rectal tenesmus, and some bladder strangury. In these severe cases the diagnosis is easy, and does not require the taking of a hæmoglobin index. The abdomen should be opened at once, and venous transfusion, of citrated blood or a glucose saline, carried out.

It is well to remember that if such a patient survive and be not seen till the fourth or fifth day she may present all the signs and symptoms of a widespread peritonitis—namely, fever, a rapid pulse, a distended abdomen with paralytic ileus, regurgitant vomiting, with a marked leucocytosis—the picture of late bowel obstruction.

In a so-called chronic case—the “leakers”—while the diagnosis is less urgent, it is sometimes more difficult to make. There is the history of repeated attacks of sharp, lancinating pain in the lower abdomen, an interval of twenty-four or forty-eight hours, or even some days, between them, slight uterine hæmorrhage, no marked fever or great disturbance of pulse rate, a lateral mass on one or other side of the uterus, increasing rapidly in size. Mark such a case. If a decidual cast is shed from the uterus—this occurs in only about 20 per cent of the cases—the diagnosis is clear.

There is in these cases a degree of anæmia, there is often a marked leucocytosis (De Quervain contends that a leucocytosis of 20,000, where signs are slight, points to a hæmorrhage rather than to an inflammation). A hæmoglobin index is of small value. Two years ago the hope was expressed that a low and falling index would reveal a concealed hæmorrhage. Unfortunately, this is not so.

We rely in these cases upon the history—the recurrent attacks of pain, the uterine bleeding and mass, at first lateral to the uterus, which increases rapidly in size. It is always well to bear that in mind. If in doubt, an exploratory colpotomy is the indication, and at once settles the matter. If blood is found, the abdomen should be opened from above and the tubal sac removed.

2 ACUTE INFECTION OF THE APPENDIX OR FALLOPIAN TUBE

The second common condition is an acute infection—an infection of either the vermiform appendix or the Fallopian tube. The distinction between these two infections is all-important, for an inflamed appendix should be at once removed, certainly within the first twenty-four hours, while to open the abdomen for an acute salpingitis is nothing short of a disaster.

The inflamed appendix we all know, with its more or less definite syndrome, outlined first by Reginald Fitz, and its surgical treatment indicated by Charles McBurney of New York. Professor Wilkie of Edinburgh emphasizes an important pathological and clinical distinction. He says

‘There are two main types of acute appendicitis (a) the one infective, an organismal invasion of the lymphoid tissue, the inflammatory type, here there is pain, more or less continuous, but not severe, fever, increased pulse rate, localized tenderness, and a marked leucocytosis, and (b) the obstructive type, faecal concretions often present, blocking of the circulation, and sudden gangrene, and perforation. Here the pain is intense and spasmodic, the fever is slight, the pulse is often rapid—the abdominal facies—and no great increase in leucocyte count.’

These are two main divisions, and I think they are well founded.

had a long and rational tradition behind it. As an art medicine had made great progress even before his day. Great minds had been studying the problems of Nature and of men long before Hippocrates, but he seems to have gathered all that was sound in the past history of medicine, his influence tended to the acquisition of all that was new and valuable, and to the casting off of all that was useless and superstitious. Hippocrates was called "the Father of Medicine," not altogether for his discoveries but because he laid down the principle on which that art was founded. In order to appreciate what he did, it is only necessary to glance at Babylonian and Egyptian medicine, or to become acquainted with the many systems common in his time. He rejected all that was useless, and founded a system based on reason and common sense. He recognized that diseases are part of the processes of Nature, that there is nothing divine or sacred about them, he was the first to recognize the healing powers of Nature, and was a great advocate of rest, pure air, exercise, and proper diet. He was a keen observer, and an active physician. He used few drugs, but placed his confidence in the restorative powers of Nature. The great contribution of Hippocrates to medicine was the art of careful observation.

One of the first medical schools of antiquity was established at Cos, an island of Greece, and here in the health temple Hippocrates practised the art. He decided that all diseases are abnormal natural conditions. He found that Nature alone often terminates disease and works a cure with a few simple medicines, and often enough with no medicine at all. The Greek health temples were quiet retreats where the sick, exhausted, and convalescent might gain the benefits to be obtained from pure air, fine scenery, sunlight, and regulated life. They were not unlike our modern sanatoria, and it is likely that cases of tuberculosis were benefited at such places. The Asklepion or health temple in which he laboured was situated about two miles from the sea, at a point where the mountains rise gently from the gradual slope of the plains. The environment was both beautiful and exhilarating. A group of noble buildings erected in the unequalled architecture of Greece took nothing from Nature, but made her resources better available for man. Here the foundations of modern medicine were laid, here the modern process of careful record, case-taking, bed-side instruction and clinical lectures were practised, much in the manner in which we see it to-day. The methods of Hippocrates have formed the basis of many departments of modern advance. His dietetic principles, especially in fevers, are substantially those of the present day, and in many ways we have returned to his simple and natural methods of treating disease.

For sixteen centuries the civilized world thought that to retain health periodic bleedings were necessary, but for the last two centuries we have gradually been getting back to the teach-

ing of the great master. We have discovered that the best results are obtained when we leave something to Nature.

Modern medical science includes bacteriology, chemo-therapy, and many other things which Hippocrates never thought of, and we would be foolish to abandon any one of our modern discoveries which go to make medicine what it is to-day, yet in some respects we might do well to take a glance back at Hippocrates. We in our age are apt to lay too much stress on bacteriological findings, and at the same time pay too little attention to the more vital part, the dissociation of the functional unity of the whole body. Unlike Hippocrates, we forget the human organism in our zeal to find out all about the enemy attacking that organism. It might be well at times to pay a little less attention to bacteria, and to give more thought to the raising of the individual immunity, both by artificial and by natural methods. We have learned that the invader finds it hard to gain a foothold when the defences are well organized, he flourishes when these are weak or temporarily inadequate. The Greeks believed in Nature as the healer of disease. They believed that human bodies are and normally remain in a state of health, and that on the whole they tend to recover from disease. In favour of this belief is the fact that there are not more than two or three microbic diseases in natural conditions, and there are no constitutional diseases in the system of wild Nature.

Modern medicine may be truly described as in essence a creation of the Greeks. They gave us our first start in rational medicine. But for ancient Greece the art of medicine could not have advanced as we see it to-day. It is hard to imagine what the state of medicine would be to-day without the works of these great men. The Greeks were the beginners of nearly everything, they were creators in the true sense of the word, and as no other people have been. The small country of Attica has given an art which all the world since has not surpassed. We are apt to wonder at times what these great intellects would have accomplished if their labours had been conducted under the same advantages which we in our time have the good fortune to enjoy. Handicapped as they were, in many departments they were unsurpassed until the nineteenth century. They were not only successful practitioners of medicine, but they were also advanced in the art of surgery. Descriptions are found in the Hippocratic writings for such surgical procedures as opening the chest for empyæma, and for trephining the skull in cases of fracture, two important operations of modern surgery. These operations, we are told, were often successful, for they were performed with skill and conducted in the pure air of the islands of Greece, far from the crowded centres, where the natural conditions were at their best. Many have wondered why the Greeks having achieved so much did not achieve a little more and antici-

pate modern science. One reason is that they were handicapped by the lack of the microscope, and other instruments of modern research, another is that Greek public opinion was hostile to dissection of the human body. It is the wonder of our age that the physicians of antiquity, though ignorant of the nature and but dimly aware of the existence of infection, could have accomplished so much. Without dissection, without any experimental physiology or pathology, and without any instrumental aid, the ancient Greeks advanced the knowledge of the cause of disease as far as it is conceivable that men in their position could do it. We thus come to realize the wonderful genius and vitality of mind of those whose works still live after twenty-five centuries, and the thought comes to our minds that it would be a great loss to the Medicine of our day if we were to forget the works of these great men. While we are employing our modern methods and testing out our present day inventions, let us at times look back to them, it may be that even yet they have something to give that might be useful to us. We do not realize how difficult it was for these great intellects, living in a world of superstition and traditional beliefs, to rise above them and yet it has been stated that the period which intervened between the birth of Pericles and the death of Aristotle is undoubtedly the most memorable in the history of the world with regard to its influence on the subsequent destinies of civilized man. In the centuries from 500 to 300 B.C. the little barren country of Attica produced twenty-five illustrious men, a greater number than has ever been seen in the whole world in any two centuries since that time. It has been a severe misfortune to humanity that the high Athenian breed decayed and disappeared, for if it had maintained its excellence and had spread over the earth it is hard to imagine what great things it would have accomplished for the good of human civilization.

In the glorious days of Pericles the Greeks were remarkable for their constancy of purpose, and the steadfastness of their ideals. Their business was to carry everything they undertook forward to perfection, their aim was to lead the mind of man toward a knowledge of the truth, to spread sound and healthy ideas, to draw human beings from the paths of prejudice and passion, and to make reason the supreme guide to public opinion. The idea of service to the community was deeply rooted in the Greeks. Their aim was to be useful, to be helpful. The aim for the enrichment of life was exhibited in them as in no other people.

Medicine among the Greeks was a progressive study for a far longer period than has been the case in the Western world. Greek medicine first took on a rational spirit with the Ionian and Italo-Greek philosophers at the beginning of the sixth century B.C., and continued to make progress until the death of Galen at the beginning of the third century of the Christian era. It

thus lasted eight hundred years. Our own system of scientific medicine has only lasted three centuries, at most, less than half the time that Greek rational medicine endured.

The earliest works that have come down to us are medical in character and bear the name of Hippocrates. The noblest expression of early Greek medical science is to be found in the so-called Hippocratic collection, which contained much material of the most scientific type. The greater part of Greek medical writings was founded on a rational basis. They endeavoured to explain the origin of disease on rational grounds and to apply remedies when possible on a reasoned basis, and, despite serious and irreparable losses, we are still in possession of some of the finest products of the Greek medical intellect. Practically all the works of ancient medicine were produced by Greek physicians. There are said to be fifty-three works in all in the famous Hippocratic collection, but of all these works not one can be definitely stated to have been written by Hippocrates himself, the books which compose this collection were probably written by different authors at dates widely separated from each other. The *Aphorisms* is the most famous book associated with the name of Hippocrates, probably the greatest medical work ever written, and is the most likely of all the collection to have been written by the "Father of Medicine" himself.

The works of Hippocrates, and later of Galen, formed the main medical legacy of Greece to the world. Galen, like the great master, was a voluminous writer. His works alone form about half the mass of surviving Greek medical literature. They cover every department of medicine, anatomy, physiology, pathology, medical theory, therapeutics, as well as ethical medicine and surgery. Galen's views of disease in general are those of Hippocrates, but in treatment he differed, for he placed great confidence in drugs. He was the greatest biologist of the late Greek period, perhaps the greatest of all time. His views prevailed in medicine until Harvey and even later. There is no ancient physician in whose writings are contained so many indications of modern methods of research. His knowledge of the heart and arteries was such that it is difficult to understand how he missed discovering the circulation of the blood. All through later antiquity and the Middle Ages the science of medicine was based on the writings of Hippocrates and Galen. With the death of Galen in the second century of the Christian era the creative period of the Greek medicine terminated, and for more than a thousand years the wonderful accomplishments of the Greeks were almost forgotten.

In the beginning of the Christian era Galen and Celsus flourished. These two famous men were educated at Alexandria. In their medical practice they both took advantage of the curative powers of the sun, but after them all persons were treated alike in physical and intellectual

night, and for a thousand years the practice of medicine was but a corrupt imitation of the teachings of the great master. The wisdom of the Greeks was in this age considered foolishness, knowledge other than that which made a man wise unto salvation was considered useless. With the advance of the sixteenth century the western world again turned its eyes to the old Greek intellectuals for instruction, and at this time the works of Aristotle and Galen became the great stimulus to the foundations of a new biological science. It is now recognized that Aristotle was one of the very greatest investigators of living Nature, he was perhaps the greatest naturalist of antiquity. His biological works excited little interest during the Middle Ages, but from the sixteenth century on they have been closely followed by naturalists. He was always found in the van of progress. For two thousand years, and throughout all lands, men have come to him and found information. While the western world sat in darkness, Arab and Moor, Syrian and Jew cherished his books. The oldest of the universities were based on his teaching and his influence still remains. It is said that no man has ever swayed such an intellectual empire as he in logic, metaphysics, rhetoric, physiology, ethics, poetry, politics, and natural history, in all a creator and in all a master. So far as we know, there was no biology worth looking at before him. The history of the human mind offers no parallel to his career, and it is the universal wonder how one man could have accomplished so much.

The activities of the Ancient Greeks are for the most part imperishable, their works are still with us, and their spirit is eternal. During the last six thousand years we have changed our form of belief, we have changed our form of clothing and our dwelling-places, but in brain and body we have changed only in minor details. We are in advance of the ancient Greeks in many ways, but yet there still remains a world beyond our senses of which we can form no conception.

DR ALEXANDER GORDON AND DAUGHTER

By W H HATTIE, M D

Halifax

Every week "An Occasional" contributes to the *Acadian Recorder* a delightfully gossipy letter dealing with the early days of Halifax. In a recent issue he reminds us, in a brief reference, of the presence in Halifax, a century and a quarter ago, of a Dr Gordon, whose own career was not marked by conspicuous success, but whose daughter was destined to a somewhat romantic life. What follows has been prepared from the scanty material available to the writer, in the hope that it may interest readers of the *Journal*.

Alexander Gordon, a native of Aberdeenshire, came from Scotland to Charlottetown, P E I in 1785, and was attached in a medical capacity to two companies of the Black Watch, then stationed at the island capital. For services rendered during the American Revolutionary War, he was given a grant of land at Charlottetown. Seemingly, he was a rather dashing fellow, fond of dress and display. He made a successful attack on the heart of Margaret Patterson, daughter of the then governor of the colony, and took her as his bride early in 1791. Four children issued from the marriage, of whom Margaret, the last to be born, gained no inconsiderable celebrity.

Gordon was at least a wee bit reckless, and became so involved financially that all his property was seized for debt, and he moved with his family to Halifax, soon after the beginning of the last century. A little later he received an appointment as apothecary to the garrison at Halifax. Within a short time he was charged with an offence for which he was court-martialled and deprived of rank and pay for six months. Before the expiration of this time the strength of the garrison was reduced, and Gordon's pay was cut in half. This was quite insufficient for the maintenance of his family, so he decided, in 1803, upon a visit to his old home in Scotland, in the hope of disposing of a little property he held there and possibly of obtaining some assistance from relatives. Acting promptly on this decision, he took with him his two daughters, Margaret and Mary, to place them with his sister, Mrs Usher, of Kirkcaldy, a widow without children and with little means, in order that they might come under the tuition of Edward Irving, a famous teacher with whom Thomas Carlyle later became associated. Gordon died during the passage, leaving his family in wretched circumstances.

The fatherless little girls were in time placed in accordance with Gordon's intentions. A small annual grant was made to them from the "Compassionate Fund" and thus gave the girls and their aunt, Mrs Usher, a combined income of about £45. Mrs Gordon supported herself and her two boys for a few years, when she married Dr Guthrie, an army surgeon.

Despite her straitened circumstances, Mrs Usher managed to have her nieces benefit by the instruction of Irving, the Kirkcaldy schoolmaster. Margaret proved to be an exceptionally apt pupil and won Irving's admiration. When Carlyle went to Kirkcaldy, he promptly fell in love with Margaret, whom long afterwards he described (*Reminiscences*) as "of the fair complexioned, softly elegant, softly grave, witty, and comely type," with "a good deal of gracefulness, intelligence, and other talent." Other references to his first love are to be found in Carlyle's writings, and it is generally believed that the original of "Blumine" (in *Sartor Resartus*) was none other than Margaret Gordon.

There is good evidence that Margaret admired

and was fond of Carlyle, but, in all probability, she was already engaged to Alexander Bannermann, of Aberdeen, to whom she was distantly related and to whom she became married a few years later. In 1851 Bannermann was knighted, and appointed to the governorship of Prince Edward Island, and in the following year Lady Bannermann returned to her native province, after an absence of just half a century, to grace the Government house which her mother had

left as the bride of Dr Gordon. A few years later Sir Alexander Bannermann was transferred to the governorship of the Bahamas, and subsequently to that of Newfoundland. Lady Bannermann was thus brought into contact with many eminent people, upon all of whom she made a deep impression by her learning, charm of manner, and sweetness of disposition. She died in London in 1878, at the age of 81 years.

Special Correspondence

The London Letter

(From our own correspondent)

The arm-chair critic is undoubtedly getting alarmed at the growth of what he calls bureaucratic medicine, and the flow of reports from Government offices on health matters, with their talk of "norms" and "data", is certainly increasing, while enthusiastic young men in the public health services are inclined to sneer at clinical medicine. All this is no doubt the inevitable accompaniment of a revolution, for a revolution is certainly in progress, and Sir George Newman, the Chief Medical Officer of the Ministry of Health, is one of the leading conspirators, with "prevention" as his pass-word. These remarks are suggested by the Annual Report for 1927 on "The State of the Public Health." In the old days such reports dealt characteristically with statistical studies of death and the revolution is seen in the proportion of the volume now devoted to the living. It is true that an infantile mortality rate of 70 per 1,000 births is mentioned but that is surely a figure of which as a nation we can be proud, our pride being tempered by the fact that puerperal mortality shows no decline and the death rate of infants under one month still remains high and shows no diminution during the last five years. Dealing with the living, the report emphasizes the value of artificial immunization against diphtheria (although the London County Council still refuses to adopt it), and mentions the increased use of scarlet-fever antitoxin. Tuberculosis receives very full consideration, especially as regards treatment and the use of B C G. This vaccine is discussed, with guarded conclusions, pending further investigations.

Sir George Newman lays down the basic principles of a sound national system of preventive medicine as collection of data, establishment of normality, investigation of the character and incidence of disease, and the national organization of health services. Such is the revolutionary creed, but the arm-chair critic may prefer to be allowed to die quietly with his bottle of medicine by his side.

It is most awkward to be a lunatic or a

mentally defective person these days, for the chances are that institutional treatment will be very difficult to obtain unless one is a rich lunatic. The shortage of accommodation for mentally diseased patients is very serious and rightly occupies an important position in the report for 1927 by the Board of Control. The number of patients resident in county and borough mental hospitals increases on an average by approximately 2,500 every year while the number of vacancies is obviously decreasing. At the moment only two local authorities are building new institutions while a large colony at Epsom, famous for its mental hospitals as well as for the Derby, has been re-opened in an attempt to deal with the problem. Such a shortage of accommodation is a serious matter for "lunatics," but even more serious for "mentally defectives," who are rather in the position of being dealt with after all available room has been filled up. This is especially serious in view of the new "Mental Deficiency Act," the most important sections of which it will be impossible to administer unless prompt action is taken. On very conservative estimates only half of the mentally defective patients requiring institutional care were receiving it on January 1, 1928. Such a position is intolerable, for mental defectives are notoriously prolific and always beget defectives, becoming veritable centres of degeneracy, disease, inebriety, pauperism and crime. Mental hospitals are too busy dealing with lunatics, even if they had space to spare for mentally defective patients, and it appears a most urgent matter for the welfare of the nation that local authorities speedily found colonies and suchlike institutions for the increasing number of cases which correct administration of the Mental Deficiency Act will entail.

The Fourteenth Annual Conference of the National Association for the Prevention of Tuberculosis was held in London during last month and was notable on this occasion for the presence of Canadian delegates. It is always difficult and invidious to pick out special papers from a conference of this sort, but for a practical appreciation of the tuberculosis problem as

it exists in England and how it should be tackled a communication by the chief tuberculosis officer for the county of Lancashire, Dr G L Cox, demands notice. He emphasized first the importance of the dispensary as an organization rather than as a mere building, and he said that the commanding officer must be paid enough to be an up-to-date specialist, working whole time at his job. The dispensary unit included notification and led on to the second link in the scheme, the institutional unit. There was only too often too little institutional accommodation available and the difficulty had been met in Lancashire by providing in each dispensary area a hospital run by the consultant tuberculosis officer and his assistants. The third link was after-care and education where the social worker was of great value. Discussion took place on Dr Cox's paper, and it was noticeable how prevention was kept very much in the foreground with a *leit motif* of housing as the first problem to be solved.

ALAN MONCRIEFF

London, November, 1928

The Edinburgh Letter

(From our own correspondent)

Dr W T Ritchie, the new incumbent of the Chair of Medicine in the University, delivered his inaugural address on Thursday, October 4th. After a generous tribute to Dr Gulland, the retiring Professor, Dr Ritchie referred in turn to the various distinguished men who had occupied the Chair since its foundation in 1685. The first three professors of medicine in the University were Sir Robert Sibbald, Dr James Halket and Dr Archibald Pitcairne. Pitcairne was the most renowned physician of his day in Western Europe, and may be regarded as the founder of the Edinburgh Medical School. He was professor at Edinburgh and at Leyden at the same time. An ardent Jacobite, on the death of Claverhouse at the battle of Killicrankie, he composed an epitaph to the memory of that devoted loyalist. In 1724, William Porterfield was selected by the Town Council to fill the Chair. His tenure was very brief and when the medical faculty was founded in 1726, Drs Sinclair and Rutherford were appointed professors of the Theory and Practice of Medicine. Rutherford was the maternal grandfather of Sir Walter Scott. He was succeeded by Robert Whytt, who was followed by John Gregory. The next professor was the illustrious Cullen. At his death in 1790, his place was taken by James Gregory, whose father had previously held the Chair. Gregory's claim to fame can only be regarded as a little less than those of Pitcairne and Cullen, though now he is chiefly enshrined in

our memories as the inventor of his rhubarb powder. James Home, who hardly lived up to expectations, followed and in turn gave place to William Pulteney Alison, the brother of the historian. The next to occupy the Chair was Thomas Laycock, an Englishman, who was mainly interested in nervous and mental disorders, working on lines similar to Charcot and other French physicians. Sir Thomas Grainger Stewart followed in 1876, and so, by John Wylie and George Lovell Gulland, we come to the present day. The appointment of a new professor to the Chair of Medicine in Edinburgh is a matter of first class importance. A survey of this galaxy of notable names will show that the new incumbent is succeeding to a heritage of fame.

Under the auspices of the National Association for the Prevention of Tuberculosis an extensive campaign of popular education is being carried on all over Great Britain. Three medical commissioners with special experience of the disease have been appointed, and are now touring the country, giving lectures and demonstrations upon every aspect of the subject. In Scotland, Dr Hailey Williams has held meetings principally in the Highlands and Islands, which for many reasons have an unenviable amount of the disease. During the past year over two hundred meetings have been held, some of them in the very remote parts of the Outer Hebrides. An interesting series of cinematograph films is shown to the people, and special competitions are held among the school children, with prizes for the best essays upon the subject of the lecture. In spite of the prejudices of the people and their conservative habits in regard to the routine of their daily life, the large attendances at the lectures have been an encouraging feature of the tour. The Scottish Highlander is well known for his intelligence. He is well able to follow a case when it is put to him, and there is reason to believe that the Association's campaign may be the beginning of new things for those who live in those remote districts. As a social problem tuberculosis is of comparatively recent origin in the Highlands. In many places there are men still living who can remember the first cases in their own village. It has all the features of a new infection spreading in virgin soil. Contemporaneous with the introduction of tuberculosis there has come a change in the nutrition of the people. Fish no longer forms the main portion of the people's food, and the milk supplies in many areas are very limited. Oatmeal, the old fashioned dish of the Highlander, now comes from the cities of the South, and white bread and tea take an undesirably prominent part in his dietary. There are signs that these facts are being realized by the more thoughtful

observers and it is the Association's policy to stimulate the growing desire for new conditions of life. The Chairman of the Executive Committee Sir Robert Philip, whose pioneer work in the prevention of tuberculosis is so widely known, is responsible for this side of the Association's work.

For a number of years there has been only one crematorium in Scotland. This is situated in Glasgow and the intervening miles have interfered with its frequent patronage by the people in Edinburgh. We are however no longer to be behind hand in this alternative expedient for the disposal of our dead. The Edinburgh Cremation Society have now acquired an option from the Town Council to purchase the house and grounds of Easter Warriston as a situation for the erection of a crematorium. This house stands on a site immediately to the east of the former residence of that Lord Warriston who was the inveterate enemy of Montrose. He was a member of the Cromwell House of Peers, and was singled out at the Restoration and hanged at the Mercat Cross (1663). King Charles II is reputed to have been particularly desirous for the execution of this "canny lynx-eyed lawyer and austere Presbyterian zealot." The house is to be adapted for the use as a chapel and for incinerating rooms. The grounds are spacious and well laid out, and lie within easy reach of one of the largest of the cemeteries in the city. The town council of Aberdeen are also con-

sidering the question of establishing a municipal crematorium in or near the city.

A well known Scotsman, and a notable product of Edinburgh Academy and University, has passed away, through the death of Professor Diarmid Noel Paton, F.R.S., the distinguished Professor of Physiology at Glasgow University. In 1886 he became Lecturer in Physiology at Surgeon's Hall, Edinburgh, and three years later was appointed Superintendent of the Research Laboratory of the Royal College of Physicians, where he succeeded the late Sir German Sims Woodhead. In 1906 when Professor J. G. McKendrick retired, he was translated to the Glasgow Chair of Physiology. There during twenty-two full years of service at Gilmorehill he inspired his students by the enthusiasm of his teaching and his interest in all medicine. The eldest son of the late famous printer Sir J. Noel Paton, he inherited artistic gifts which he used to full advantage in illustrating his lectures. Some of us in Edinburgh remember him not only as a famous scientist and brilliant teacher, but also as one of a distinguished band, which thirty years ago made an annual golfing holiday at the New Year to Machrihanish in Argyllshire, and which included D. J. Cunningham, John Chiene, Robert Muir, Ralph Stockman, G. A. Gibson, Sir James Hodsdon, Sir Edward Sharpey-Schafer, and F. D. Boyd.

Medical Societies

ONTARIO MEDICAL ASSOCIATION

ANNUAL MEETINGS OF DISTRICT SOCIETIES

District Number One

District Number One met in annual session on October 26th, with an attendance of 160. The District Counsellor, Dr. J. D. Curtis, of St. Thomas, presided.

The first item on the program was a heart clinic by Dr. John Oille of Toronto. Following this, Dr. Omar Wilson, of Ottawa, conducted a skin clinic. The two clinics proved intensely interesting, as was also the address on "Goitre," given immediately afterwards by Dr. R. V. B. Shier, of Toronto.

An address by Dr. E. A. McQuade, of Trenton, President of the Ontario Medical Association, was delivered in the evening. Dr. Robert T. Noble of Toronto, the official representative of the College of Physicians and Surgeons of Ontario, gave a talk on the Medical and Narcotic Drug Acts, setting forth

some of the difficulties which have arisen out of their attempted enforcement, and affording an opportunity of clearing away many misunderstandings. Following discussion on the Narcotic Drug Act and the care of drug addicts, a resolution was passed memorializing the provincial government to provide adequate hospital accommodation for all such, and also to make provision for their committal thereto.

The closing address was given by Dr. T. C. Routley, Secretary of the Ontario Medical Association, calling attention to several matters affecting the welfare of the medical profession of this province.

A brief business session was held at which Dr. J. D. Curtis, of St. Thomas, was unanimously nominated for Counsellorship of the district. The following Vice-counsellors were elected for the ensuing year: Dr. F. W. Luney, London, Dr. G. F. Lewis, Windsor, and Dr. J. A. Bell, Sarnia. A very cordial invitation was extended by the medical men of Windsor for the district meeting to be held in that city in 1929.

District Number Three

District Number Three, comprising the counties of Bruce, Grey and Dufferin, met in annual session at Owen Sound, on October 10th, with an attendance of about sixty doctors and forty ladies. The Counsellor, Dr Malcolm Stalker, of Walkerton, was in the Chair.

The program commenced in the afternoon with an address by Dr H K Detweiler, of Toronto, on "Diagnosis of diseases of the blood and blood-forming organs." This was followed by an address on "The goutie problem in general practice" by Dr Roseoe Graham and a talk on "Polomyelitis" by Dr Geo F Boyer, of Toronto. During the afternoon, the ladies enjoyed a game of golf and afternoon tea at the golf club, later joining the doctors at dinner in the Y M C A. Following the dinner, Dr E A McQuade of Trenton, President of the Canadian Medical Association, gave a brief address on matters pertaining to organized medicine. Dr Robert T Noble gave an interesting review of the Medical and Narcotic Drug Acts, stressing some of the many difficulties which have arisen out of their attempted enforcement. Considerable discussion followed with reference to the necessity of some provision being made for the care of drug addicts, and a resolution was heartily endorsed by all present memorializing the provincial government to provide adequate hospital accommodation for such cases, and also to make provision for their committal thereto.

The closing address of the evening was given by Dr T C Routley referring to many points of interest to the medical profession of the Province of Ontario at the present time.

A short business session was held at which the following nominations were made for Counsellor of the District: Dr S T White, Orangeville, Dr T H Sneath, Brimmore, and Dr Malcolm Stalker, Walkerton.

The following were elected Vice-counsellors for the ensuing year: Dr T H Sneath, Brimmore, P F McCue, Walkerton, and H W Baker, Grand Valley. It was decided that the next annual meeting of the district should be held at Orangeville.

District Number Four

The annual meeting of District Number Four was held in the Hamilton General Hospital on October 25th, and was one of the best attended and most enthusiastic meetings ever held in this district, there being 210 members of the profession present from the city and surrounding counties.

At 9:30 a.m. Professor A M Shipley, of the University of Maryland, Baltimore, conducted a clinic on head injuries and surgical condi-

tions of the chest, after which the following excellent papers were contributed by three Hamilton men: "Scoliosis," by Dr Ernest Jones, "Congenital hypertrophic pyloric stenosis," by Dr Frank Boone, "Bronchial asthma," by Dr William D Swan. Dr Campbell Howard, of Montreal, then conducted a clinic on typhoid fever and on rheumatic fever and its complications.

At 12 o'clock, those present were entertained to luncheon at the hospital, as guests of the Board of Governors, after which Dr T C Routley gave an address in which he referred to many matters affecting the welfare of the medical profession of Ontario.

In the afternoon, Dr Harry Whitlock, of Hamilton, gave a paper on "The acute ear," followed by an address by Dr Otto W Neumeier on "The open reduction of fractures." Dr A M Shipley, of Baltimore, then gave a clinic on "Genito-urinary diseases in older men," after which the following papers were read by local men: "Irregular tachycardia," by Dr Richard Weaver, "Pituitary tumour," by Dr Roswell Park. Following this, Dr Campbell Howard gave a second clinic, this time dealing with primary and secondary anaemia, Banti's disease, and purpura hæmorrhagica.

In the evening an address was given by Dr E A McQuade, of Trenton, on matters pertaining to medical organization.

Dr Robert T Noble gave a talk on the Medical and Narcotic Drug Acts, dealing with some of the difficulties which have arisen out of their enforcement.

This was followed by a very excellent address by the Hon W H Price, Attorney-General of Ontario, on "The medical profession and the law."

At a short business session, Dr J H Holbrook of Hamilton, was nominated for the Counsellorship of the district, and Dr W K Colbeck, of Welland, was elected Vice-counsellor.

This completed the program of one of the best district meetings ever held in the province. The clinics conducted by Drs Howard of Montreal and Shipley of Baltimore were extremely interesting and very highly appreciated, as were also the cases presented by members of the district.

District Number Five

A meeting of District Number Five, comprising the counties of Ontario, Simcoe, Peel, and York (including the city of Toronto), was held at Barrie, on October 3rd, under the auspices of the Simcoe County Medical Association. This was the first occasion that this conference has been held outside the city of Toronto and many of those present expressed pleasure with the results of the experiment.

Dr G D McLean, Woodbridge, Counsellor, presided. The first speaker in the afternoon was Dr Robert T Noble, who gave a very interesting review of the Medical and Narcotic Drug Acts, and outlined many of the difficulties arising out of their attempted enforcement. After some discussion, the following resolution was directed to be forwarded to the Government from this district —

Whereas it is the opinion of this meeting that drug addicts should receive hospital care, and

Whereas there is no provision made for these in the hospitals of this Province, we would respectfully request the Provincial Government to provide adequate hospital accommodation for such cases, and also to place on the statute books the necessary legislation covering their committal thereto — Carried

The next speaker was Dr J K McGregor of Hamilton, who spoke on "Factors contributing towards reduction of surgical failures." The third speaker of the afternoon was Dr Geo S Young, of Toronto, who gave a very interesting and instructive paper on "Hypertension." He stressed the importance of watching the diastolic blood pressure.

Very interesting addresses were given in the evening by Dr E A McQuade, Trenton, and Dr T C Routley, Toronto, and were interspersed by enjoyable vocal numbers by Miss and Miss Laidman, Barrie. Mr F Krait, Barrie, pleased the audience with solos on the violin and clarinet.

After recommending that the name of Dr W A Lewis, of Barrie, be placed in nomination for Counsellor at the annual meeting of the Canadian Medical Association, and electing Dr S W Otton, of Newmarket, as Vice-counsellor of this district, the concluding speaker of the evening, Dr F S Patch, of Montreal, gave a delightfully instructive and interesting talk on "Some aspects of the prostatic problem." This was accompanied by lantern slides and the subject was dealt with in such a manner as to be fully appreciated and enjoyed by the general practitioner as well as the trained urologist.

District Number Six

The annual meeting of District Number Six, was held in Belleville on September 27, 1928. There was a large attendance of the medical men of the district, and a splendid program was much enjoyed. The day was fine, and many of the doctors were accompanied by their ladies, who were looked after by Dr Emma Commor. The meetings were held in the Hotel Quinté, commencing at 9 30 a m.

During the morning session, most interesting papers were read by Dr MacGregor, of Kingston, on "Celiac disease", Dr H B VanWyck, of Toronto, on "Toxæmia of pregnancy", and Dr F J Tees, of Montreal, on "Difficult fractures." At 12 30 lunch was served, and at the afternoon session the following addresses

were enjoyed "Some clinical problems in disease of the kidney," by Dr John A MacGiegor, of London, and the "Surgical abdomen," by Dr A L Lockwood, of Toronto. During the course of the evening dinner addresses were given by Rev Dr Bishop, Principal of Alberta College, Belleville, Dr E A McQuade, and Dr Robert T Noble. The latter spoke on the subject of the Medical and Narcotic Drug Acts. Owing to illness, Dr T C Routley was unfortunately unable to be present, and was much missed by the meeting.

A resolution was passed that the Government be asked to provide facilities for the treatment of drug addicts and alcoholics.

Dr F C Neal of Peterborough and Dr George H Stobie of Belleville were re-elected Counsellor and Vice-counsellor for District Number Six for the ensuing year.

District Number Seven

On Wednesday, October 31st, the annual meeting of District Number Seven was held in Kingston, with an attendance of 125 medical men from Kingston and surrounding counties.

The morning session, which was held in the General Hospital and was presided over by Dr L J Austin, consisted of a number of very interesting clinical cases presented by members of the district.

The afternoon session opened with an address by Dr Roscoe R Graham of Toronto on "Surgical aspects of thyroid disease." This was followed by an address by Dr T C Routley, touching on many matters of interest to the medical profession at this time. Dr I M Rabinowitch, of Montreal, then gave a paper on "Diabetes." The last address of the afternoon was given by Dr W P Tew, of London, on "The management of certain obstetrical difficulties."

A banquet was served at 7 30, followed by an address by Dr E A. McQuade, on matters pertaining to medical organization.

Dr Robert T Noble gave a brief review of the Medical and Narcotic Drug Acts, which proved very interesting to those present. Dr Noble called attention to some of the difficulties which have arisen out of the attempted enforcement of these acts. Considerable discussion ensued with reference to the care which should be given drug addicts, and a resolution was passed memorializing the Government to provide adequate hospital accommodation for all such, and also to make some provision for their committal thereto. The final address of the evening was given by Dr L J Austin, of Kingston on "The kings of France and their fatal diseases." This was very much enjoyed by all.

At the brief business session which was held, Dr L J Austin, of Kingston, was nominated for the Counsellorship of the District, and Dr

W A Jones, of Kingston, was elected Vice-counsellor for the ensuing year.

This concluded one of the most interesting and enjoyable annual meetings ever held in District Number Seven.

District Number Eight

The annual meeting of District Number Eight was held in Ottawa on October 24th. The morning session opened at 9 o'clock at the Civic Hospital, the Counsellor, Dr W S Lyman, of Ottawa, in the chair.

Dr F H MacKay, of Montreal, was first on the program, with a paper on "Poliomyelitis." This was followed by an address on "Thrombo-angitis obliterans" by Dr Donald A Hingston, of Montreal.

At 1 o'clock, luncheon was served at the Chateau Laurier. During the luncheon hour, a short business session was held at which Dr W S Lyman, of Ottawa, was nominated Counsellor and Dr J C Woods was elected Vice-counsellor for the ensuing year. Immediately following the luncheon, Dr E A McQuade gave a brief address, after which Dr Robert T Noble, gave a review of the Medical and Narcotic Drug Acts, stressing some of the difficulties which have arisen out of their attempted enforcement. This was followed by a talk by Dr T C Routley, touching upon many matters of importance to the medical profession at the present time.

At 3 o'clock, the meeting adjourned to the General Hospital, where an address on "The treatment of headache" was given by Dr Walter G Penfield, of Montreal, followed by a paper by Dr H B Cushing, of Montreal, on "The prevention and treatment of scarlet fever."

This was one of the best attended meetings ever held in this district, there being 175 members present from Ottawa and the surrounding counties. That the very excellent papers were thoroughly enjoyed by those who heard them was evinced by the splendid discussion which followed. It was the unanimous opinion that the meeting was a decided success, both from the social and scientific point of view.

THE PRINCE EDWARD ISLAND MEDICAL SOCIETY

Dr A Stewart, surgeon, and Dr R R Struthers, paediatrist, both of Montreal, delivered the extra-mural lectures before the Prince Edward Island Medical Society on October 24th.

Dr Stewart dealt in a very interesting and lucid way with the difficult subject of pulmonary suppuration. The various methods evolved during the past few years, such as bronchoscopy, for diagnosis and drainage, phrenic evulsion, thoracoplasty and the cauterization lobectomy have placed in the hands of the skilled surgeon

a varied and scientific armamentarium for attacking these hitherto unsatisfactory problems.

His afternoon paper dealt with diseases of the anus and rectum. He emphasized the importance of a careful history and physical examination, particularly digital examination of the rectum, as well as the more modern barium series and proctoscopic examination. He advocated the clamp and cautery operation for hæmorrhoids, and strongly deprecated the injection of chemicals in this condition.

Dr Struthers in the morning spoke on "Tuberculosis in childhood." He traced the tuberculosis bacillus from the time it was aspirated until it reached the tracheo-bronchial nodes, producing the usual pathological lesions, and from where it might spread by breaking into the bronchial tree, by way of the lymph channels or by the blood stream, by these latter channels, also, producing acute miliary tuberculosis with its predominant manifestation, tuberculous meningitis. The chief symptoms were fatigue, loss of appetite, weight and colour, a peculiar two-tone metallic cough and a temperature above 100° F. These were supplemented by the signs of anaemia and malnutrition, together with vertebral dullness below the first dorsal spine, x-ray evidence of enlarged tracheo-bronchial nodes and the tuberculin reaction. He had not found D'Espine's sign very useful. The bovine type, localizing in cervical and mesenteric glands, showed similar evidences of malnutrition, but milder in degree. This type caused only 10 per cent of the deaths in childhood. The treatment was that of adult tuberculosis, rest, fresh air, good food plus cod liver oil, and the quartz lamp in glandular types.

In the afternoon, Dr Struthers discussed the feeding of the normal infant. He set forth a few simple rules from which an ordinary feeding formula could be easily calculated. (1) The total fluid intake should average two and one-half ounces per pound of body weight per day. (2) The amount of milk necessary to supply the needed protein, fat, carbohydrate and salts was about one and one-half ounces per pound of body weight. (3) The total amount of nourishment in calories.

The infant's basal metabolic needs were about 27 calories. To this must be added sufficient to provide for activity, growth, etc., which brought the total up to 45 or 50 calories per pound of body weight per day. After the total fluids and milk requirements were fixed, the remainder of the calorie needs were supplied by adding sugar. At 5 to 6 months cereals and strained soups are added, and at 9 months, vegetables and additional protein in the form of hard-boiled egg and crisp bacon. Dr Struthers also discussed the usefulness of protein milk and various soured milk mixtures in the treatment of fermentative diarrhoeas.

Dr Stewart and Dr Stinther gave us material which has been of immediate value in our practice. Few lectures since the extramural courses started have been received with such enthusiastic appreciation.

T. W. McKEVITT

THE REGINA DISTRICT MEDICAL SOCIETY

On November 14th, the Regina District Medical Society, held its regular monthly meeting. This took the form of a banquet in honour of Dr M. M. Seymour, who for many years has been Deputy Minister of Public Health. Dr Gorell, in eloquent terms, proposed a toast to the guest of the evening. He recounted very many distinguished services rendered by Dr Seymour, both as a medical practitioner and as a public health official. He also referred to the many honours which have been conferred on him. This was very ably seconded by Dr F. W. Hart of Indian Head, and was drunk amidst great enthusiasm.

Dr A. MacG. Young, General Secretary of the Saskatchewan Medical Association, brought greetings from the Saskatoon District Medical Society, and also, on behalf of the profession, spoke in terms of praise of the excellent work done by Dr Seymour, and wished him health, happiness and prosperity in his new surroundings. Dr O. E. Bothwell, district representative on the Council of the College of Physicians and Surgeons, also spoke along similar lines.

Dr W. A. Thomson, Regina, who had known Dr Seymour ever since he had come to the city of Regina recounted many of the incidents which had occurred in the last quarter of a century, and gave many personal reminiscences. Dr J. C. Black, a former assistant to Dr Seymour, also spoke briefly.

On behalf of the Regina District Medical Society, the President, Dr R. O. Davidson, in a few well chosen words presented Dr Seymour with a beautiful silver serving-tray, suitably engraved.

When the guest of the evening rose to respond he was visibly affected by the many expressions of good will to which he had just listened. He recounted his experiences from the date of his graduation, which was 1879 up to the present time. Many incidents of which he spoke were of a most humorous character, and others were of a very different order, which not only greatly affected the emotions of the speaker but also his audience. At the conclusion of his address he presented the Regina District Medical Society with a photograph of the last Medical Council of the College of Physicians and Surgeons of the North West Territories, of which he was President. In the near future Dr Seymour and his family intend to reside in Orange, California.

Dr H. C. George, then presented a very intricate and complicated case of intestinal disorder simulating typhoid fever. This evoked a good deal of discussion and was greatly appreciated by all present.

Topics of Current Interest

THEORY AND EXPERIENCE IN MEDICINE

"Sir Arthur Keith addressed the annual meeting of the Chartered Society of Massage and Medical Gymnastics, held in London on October 5th, on the conflict between theory and experience in the practice of medicine.

He began by recounting an incident in his early career, forty years ago, when, in the company of an old practitioner, he visited an upland farmhouse in Aberdeen to see a patient who was prostrate with deep-seated pain in the back. The practitioner proceeded, by dry cupping, to dilate the superficial vessels, and brought about complete relief. Here, to the young man's astonishment, science and empiricism were shown in conflict, and empiricism won, hands down. That was typical, said Sir Arthur Keith, of the conflict which had been going on in medicine for centuries. In any medical journal of any period

would be found articles in which the competing claims of science and empiricism were canvassed. It was out of such conflict that medicine advanced to higher things. Young men and women entered the profession with high resolves to make science their sole guide in practice, and soon discovered themselves involved in this conflict. The conception which he himself had formed of science at the time he entered medicine was represented by the kind of knowledge which had been revealed by Pasteur or by Koch in their respective spheres. He set out with the idea that science was creative and should always precede practice, and he had gone a long way on his medical journey before he discovered that he had formed an altogether wrong conception of science. Science performed her best service, not by moving ahead of practice, but by following in the rear. Cod-liver oil furnished a homely example, it had been used by medical

men for generations, though science found no virtue in it, and then, in modern days, came the discovery of its particular value, to justify the medical faith which had been born of experience. During the long and dry winter in Newfoundland the natives lived on salt pork, margarine, and preserved vegetables, in the spring many of them suffered from night blindness. The popular remedy was bird's liver, raw or cooked. Twenty years ago this would have been thought an example of superstition, but again science had provided the justification. Captain Cook's exacting dietetic rules for his crew, whereby the sailor who refused to eat his ration of vegetable hash suffered stripes on his bare back, were successful at the time and had since been justified by the scientific explanation forthcoming in the twentieth century. Edward Jenner found by experiment that he could confer on human beings immunity from small-pox by inoculating them with cow-pox. Jenner could not explain it in scientific terms, but the method he had employed empirically was employed afterwards scientifically by Pasteur, though science had not even yet ousted experience in treatment by immunization. Quinine, digitalis, opium, arsenic, mercury, and many other useful drugs had been brought into treatment, not as the result of scientific inquiry, but of chance discovery. The value of light as a therapeutic agency of the highest value was not a modern discovery, for there never had been a time when human beings did not instinctively bask in the sun. Science played a twofold part in medicine, sometimes moving ahead of practice (as in glandular therapy), and sometimes justifying experience, so that science and experience ultimately became reconciled. It might be said, then, that there was no real conflict, but there was real conflict between magic or superstition on the one hand and science on the other—a conflict in which there could be no compromise or reconciliation.

The body was endowed, said Sir Arthur Keith in conclusion, with certain recuperative powers, and all that science could do was to assist them. But these powers came into exercise also after the charlatan had had his innings, and for this circumstance, of course, the charlatan took the credit. There were numbers of people in this country as superstitious, in a medical sense, as the natives of Africa who believed in their rain-doctors, and when the rain came gave all the credit to the magician, while the thunder-cloud received none — (*Brit M J*, 1928, ii, 674)

MEDICINE AND FLYING

"Sir Samuel Hoare, Secretary of State and President of the Air Council, after presenting the prizes at the London Hospital Medical

College and Dental School on June 29th, made some interesting remarks on the contacts between the new profession of flying and the ancient profession of medicine. He said that there was no profession in the world which demanded a higher standard of physical and nervous efficiency than flying. As the Royal Air Force had developed, the old tests which had proved sufficient for the Army and Navy were quite out-distanced, and it was soon evident that the man who had what the insurance companies would call a first-class life was by no means necessarily a good pilot. Other tests had to be superimposed, and the medical officers of the Air Force had accordingly gone to work in a special way. Instead of merely ascertaining that a candidate for a commission was free from any obvious disability or disease, they had worked out some special tests for the efficiency and co-ordination of brain, eye, hand, and foot. Sir Samuel Hoare mentioned that a short time ago he himself went through these tests, and he was glad to report that, notwithstanding five years' work in the Cabinet, his eyesight was classed in the same category as that of Mr. Jack Hobbs, the well-known professional cricketer, who had been examined shortly before. But he was excelled by Lady Maud Hoare, who accompanied him in his flight to India and back, in respect of co-ordination of movements of hands and feet, excellences which he attributed to her habit of continual motor-driving in London. The tests applied to candidates at the medical stations were supported in a remarkable degree by reports received afterwards from the units to which the newly commissioned officers were sent. This series of tests had been developed not from theory but from practice. The men who had proved themselves to be the best pilots were taken and then qualities analysed, and the result of the analysis was made the standard for application to subsequent candidates.

Sir Samuel Hoare pleaded that the medical services of the Air Force should be considered not only as an integral part of the "new arm," but as an important branch of the medical profession. He mentioned also the services which the aeroplane itself was rendering as an instrument of first aid. During some recent military operations in a difficult mountainous region of Kurdistan, about one hundred men of the regiment fell ill of dysentery. Thanks to the Royal Air Force, every one of those men was transported with the utmost swiftness to the hospital at Bagdad—an operation which otherwise than by air would have involved days of painful journeying—where they all completely recovered. One of the principal sheiks of the desert, a man who had lived his life under similar conditions to the patriarchs of

the Old Testament, went down with pneumonia. An aeroplane was sent to his assistance, he, too, was conveyed to the hospital at Bagdad, and made a good recovery. The aeroplane, besides being an instrument of defence and of civil transport, was specially well adapted for ambulance purposes. Some of the fastest aeroplanes were now being equipped in such a way that they could easily accommodate stretcher cases, and Sir Samuel Hoare said that he himself had recently flown in one of these machines a distance of two hundred miles in sixty-eight minutes" (*Brit M J*, 1928, II, 25).

THE AUSTRIAN LIP

"In a well-known passage of his autobiography Edward Gibbon wrote 'Our immortal Fielding was of the younger branch of the Earls of Denbigh, who draw their origin from the Counts of Habsburg, the lineal descendants of Eltrico in the seventh century Duke of Alsace

The successors of Charles the Fifth may disdain their brethren of England, but the romance of *Tom Jones*, that exquisite picture of human manners, will outlive the palace of the Escorial, and the imperial eagle of the house of Austria.' Unluckily the romantic legend of the common origin of the Fieldings and the Habsburgs has been destroyed by the researches of the late Mr J H Round, but this noble tribute to the genius of Henry Fielding remains in untarnished splendour. The prophecy has in part been fulfilled, for although the palace of the Escorial seems likely yet to outlast many centuries, the imperial eagle has taken wing into the limbo of lost causes and has gone, as a national emblem 'for good,' while *Tom Jones* is still reprinted and delights successive generations of readers.

There is, however, a characteristic of the house of Habsburg, to which Gibbon did not allude, which seems to be as persistent as its coat of arms or its Spanish palace. This is that combination of traits of feature which is known as the Habsburg lip, from the fact that a prominent or hanging lower lip is the most obvious of the peculiarities which constitute this family type.

In an elaborate study of the heredity of the stigmata of degeneration Dr V Galippe of Paris published in 1905 a well-documented research dealing chiefly with the house of Habsburg and its origins*. He showed that the peculiarity of the Habsburg lip depends principally on a disproportion and want of adaptation between the upper and lower jaws—that its subjects are underhung, in fact—while at the same time there is a lateral compression of the mandible which tends to render the angle be-

tween the two horizontal rami more acute than normal. This deformity French anatomists call *inferior prognathism*. It must not be confused with the prognathism which is a character of the lower races of mankind and which involves a projection of both jaws beyond the vertical line of the ideal orthognathous skull. Without attempting to follow all the footsteps of courtly genealogists who have professed to find the roots of the Habsburg family tree in the year 690, Dr Galippe goes back to the fourteenth century and begins with a traditional portrait of Ernest I, Duke of Carinthia, which he says shows inferior prognathism. This is succeeded by some 250 portraits, the series only ending in quite recent times and including the unfortunate Archduke whose murder started the world war. In nearly all these portraits, among which are included those of our Stuart kings, Dr Galippe sees inferior prognathism, in many cases where it must be confessed that a less enthusiastic observer would only see that fullness of the lips which some artists gave to their sitters as a beauty. Dr Galippe is on firmer ground when he argues that a deformity such as that shown by the Emperor Charles V has been perpetuated by the inbreeding which has been carried to such a pitch by his descendants and collaterals, although few of them showed the peculiarity in so marked a degree as he did, yet it appeared in an extreme form in the Emperor Leopold I (1640-1705), and as late as 1817 in the Archduke Albert Frederick Rudolph who died in 1864.

The basic deformity in the typical Habsburg skull is, according to Dr Galippe, a lateral compression with corresponding expansion in the antero-posterior direction causing, or at least associated with, exophthalmos. He does not mince matters in discussing the royal and noble families of Europe, nearly all of which were tainted with Burgundian blood, and, according to him, few of them of moral worth, and many of them of feeble intelligence, but after making full allowance for prejudice we must admit on the evidence that the Habsburg lip seems to be a dominant peculiarity, which crops up again and again, even among remote collaterals.

Dr Galippe shows also that a similar deformity existed independently in a marked form among the Medici of Tuscany, although the deformity in this great mercantile family was not derived from any of the sources of the Habsburgs, it was enhanced by intermarriage with that family. It is most obvious in the portrait of Cosmo III by Westerhout, and is unmistakable in that of the first Grand Duke Francis, and in many other members of that family.

Dr Rubbrecht, of Bruges, has studied this question from a slightly different point of view—that of the connoisseur of paintings and

* *L'Hérédité des Stigmata de Dégénérescence et les Familles Souveraines*, par le Dr V Galippe, membre de l'Académie de Médecine, Paris. Masson et Cie, 1905.

sculpture—and he published the results of his research in a beautifully illustrated work* in which he discusses all the available portraits and images of the early members of the reigning families of France, Burgundy, and Austria, and especially the collection of portraits which formed the exhibition of the Golden Fleece at Bruges in 1907, to which pictures were sent on loan from various galleries, including the Royal collection of Windsor Castle, whence came a very notable portrait of the Emperor Charles V by a Flemish master. This portrait, for the faithfulness of which there is strong corroborative evidence, shows the deformity in its most acute degree. The brother of Charles, Ferdinand I, had also a very full and typical lower lip. When it is remembered that the Emperor Charles married his first cousin, and that his daughter and her son did the like, and that such consanguineous marriages were frequent in the family, it is easy to understand the persistence of the Habsburg lip.

From his iconographical studies Dr Rubbrecht comes to the conclusion that the Habsburg family inherits inferior prognathism from the royal houses of Spain and Austria, but that the large lower lip existed in the families of Burgundy and Spain before their union with that of Austria, and, further, that the lateral flattening of the skull, the long nose, and prominent eyes may be found in the ancestors of the Habsburgs in the houses of Burgundy, Spain and Austria.

To the student of heredity both these books are of great interest. It is easy to understand the persistence of a hereditary trait in a race which bred in-and-in for so many generations, but it is less easy to explain the persistent fecundity of the race under such conditions"—(*Brit M J*, 1928, ii, 763)

RADIO-ACTIVE WATERS

"Dr C W Prowd, a Vancouver citizen whose reputation as a radiologist, in technical circles at least, is now nation-wide, recently delivered before the Canadian Club an address that was clearly the outcome of keen observation and quiet, sane, reflection. He has recently returned from the World Conference on Radiology held in Stockholm, Sweden, last July. Four significant thoughts stood out in strong relief and attracted the attention of his auditors. He commented on the striking fact that the very generation which first saw the scientific discovery of x-rays, the basis of the whole science of radiology, should also see a conference of twelve hundred delegates, representing all the civilized countries of the world, assembled in a

Scandinavian city to exchange ideas on the practical application of these self-same rays and of radium to modern curative art. He recounted incidents of his tour of Europe, which had been made by aeroplane, because, as he said, a careful examination of statistics showed him that this was the safest method of travel in the middle European countries. He admitted the delights and beauties of his continental tour, but added that they had been surpassed by those of the south of England when he finally concluded his anti-trip by flying from Paris to Gloydon. Then, to the delight of his audience, he drew the whole chain of thought to a close by giving it as his considered opinion that the people of Vancouver need not go away from home with the idea that they can anywhere else find anything better.

Perhaps the most interesting part of Dr Prowd's address, from a purely local standpoint, lay in the emphasis he gave to the value of British Columbia's radio-active hot springs. It had caught his attention, while in Europe, that large amounts of capital were being assembled to exploit their curative waters. None of the latter, he found, were superior to those of British Columbia. A tourist can leave Vancouver by motor car and at the end of each day find a resting place at a hot springs, with full radio active properties, already equipped with good accommodation—Harrison, Haleyon, the Windermere and Banff. Some days, Dr Prowd thought, each of these places would be a Mecca for thousands in search of health and pleasure. Their value, enhanced by the scenic beauty of the country to be traversed in order to reach them, will undoubtedly prove a real asset to the whole province"—(*The Vancouver Sun*)

ULTRA-VIOLET RAYS AND CLOTHING

"The health-giving ultra-violet rays of sunlight, which everybody wants nowadays, pass through cotton, linen and rayon fabrics about equally well when these are of equal weight and closeness of weave. Fresh, white, natural silk is almost as transparent toward the rays as bleached cotton, while wool is only about half as transparent. These are some of the results obtained in a study of the transmission of ultra-violet radiation through various fabrics, conducted at the U S Bureau of Standards by Dr W W Coblentz, Dr R Stair and Dr C W Schoffstall, and reported in the bureau's new *Journal of Research*. "In all cases when the fabric is dyed, or slightly yellowed with age, the ultra-violet transmission through the thread is greatly decreased. Hence, as is to be expected in comparing various kinds of dyed fabrics, the one having the largest openings between the threads transmits the most ultra-violet"—(*Science Supplement* Nov 2 1928)

THERMAL CONDUCTIVITY OF GLASSES TRANSMITTING ULTRA-VIOLET LIGHT

"Increased knowledge of the beneficial therapeutic effects of ultra-violet light upon living organisms has in recent years led to the development of a number of glasses which transmit ultra-violet light more or less completely. It is evident that if any of them are to replace the window-glass now being used they must

be very poor conductors of heat, for otherwise man might pay dearly for the benefits secured by the use of these glasses because of the greater amount of heat they would allow to escape from a room by conduction. The thermal conductivity for a number of these glasses has been determined at the Iowa State College by Christiansen's method. It was found that for every glass tested the thermal conductivity was less than for window-glass." —(*Science Supplement*, Nov. 2, 1928)

MEDICINE

Vitamin A as an Anti-Infective Agent Green, H. N. and Mellanby, D., *Brit. M. J.*, 1928, ii, 691

This is an important article as it is an attempt on an experimental basis to determine the exact nature of vitamin A.

Vitamin A has always presented special difficulties in assigning to it a clinically descriptive term, because it has depended to such a large extent on a purely physiological criterion, namely, growth in young animals, for its detection. It is often, therefore, referred to as the "growth-promoting" vitamin. Since the recognition of vitamin D (the anti-rachitic vitamin) as an entity distinct from vitamin A those familiar with nutritional work have felt that to call vitamin A the "growth-promoting" vitamin is a misnomer, for good growth often takes place in its absence if the diet is otherwise complete. From the early days of its recognition it has been thought that vitamin A was concerned with resistance to infection, at least of a specific type.

The authors review very briefly the papers of Mori and Bloch in regard to the association of the rare condition of xerophthalmia with deficiency of vitamin A, and the work of Drummond, Cramer and Kingsbury, and Steenbock, on the susceptibility to lung infections of animals fed on diets deficient in vitamin A. An interesting feature is that actual histological changes occur in certain of the tissues as a result of the lack of vitamin A, as indicated especially by the researches of Goldblatt and Benischek, which showed that a metaplasia occurred of columnar, cuboidal, and transitional epithelium into the squamous keratinizing type in such cases. In view of the fact that practically all of the experimental work, except that of Goldblatt and Benischek, was vitiated by the fact that the diets employed were deficient in vitamin D and often vitamin C, in addition to lacking A, the authors felt it was desirable to repeat the work under more exact conditions. The production

of vitamin D by irradiation of ergosterol made it possible to prepare diets deficient only in vitamin A.

The animals deprived of vitamin A all died with some form of infection, and the observations were made certain by careful post mortem examinations. The results are most interesting. Animals deprived of vitamin A, but receiving vitamin D and vegetable maitaine, developed, in various proportions, xerophthalmia, abscesses of the tongue, infections of the alimentary tract, nasal sinuses, or the middle ear. None of this group, however, developed infection of the kidneys or bladder, nor did they develop vesical calculus.

A second series of animals, deprived of both vitamins A and D developed the same conditions, but some few of them, unlike those of the first series, developed infections of the kidneys and bladder and vesical calculus.

A third series of animals were deprived of vitamins A and D, but given heated wheat-germ, fat-extracted wheat-germ, ergot, and fat-extracted ergot. They likewise developed the same conditions as did the animals of the second series, but this further striking feature was elicited, that the animals whose diets contained ergot had a special tendency to form calculi in the kidney pelvis.

The authors conclude that practically all animals deprived of vitamin A die of some infection or pyogenic lesions. In the control animals receiving vitamin A these lesions are absent. The administration of vitamin D does not prevent the occurrence of the lesions described and seems to be unrelated to resistance to infection.

A. G. NICHOLLS

The Nervous Complication of Measles, with a Summary of the Literature and Twelve Additional Case Reports Ford, F. R. *Johns Hopkins Hosp. Bull.*, 1928, xlii, 140

Severe cases of measles may present drowsiness or even stupor, developing on the 4th to 6th day of the eruption and disappearing with-

out any residuum. This is usually associated with a secondary rise in the temperature. There may be muscular twitchings and even convulsions, and a striking feature may be the excessive irritability. The spinal fluid is usually under pressure, but the cellular content is not greatly increased, and the globulin tests are faintly positive or are negative. Such symptoms as these are usually grouped under the term "meningism", but it is evident that they point to the brain and not the meninges. There is, however, usually an absence of focal signs, and recovery is prompt and complete. They suggest an intoxication of the nervous system without anatomical lesions.

In this review on the subject of the nervous complications of measles by Ford, he has collected all the reported cases in the literature and has added twelve more. He finds that several types occur. There is the diffuse intoxication mentioned above. Next, there are those with definite focal cerebral symptoms, usually multiple. The clinical picture in these may resemble epidemic encephalitis, or tuberculous meningitis, and it may be difficult to distinguish between them at first. In a large percentage of these cases there are residual mental defects. Epilepsy followed in four cases. Five of the patients died.

In a third group he places single focal cerebral lesions, in which hemiplegia and aphasia are the commonest symptoms, although it is to be noted that these are sometimes the residual manifestations of diffuse original symptoms. Sometimes, however, it may appear without warning, as if due to a single vascular lesion.

Another distinct and interesting group is that with cerebellar involvement, resulting in acute ataxia. Measles, indeed, is the cause of a fairly large percentage of the acute ataxias of childhood. One author is quoted by Ford as finding that 8 out of 31 cases of acute cerebellar ataxia in childhood had followed measles. The ataxia is usually generalized, but may be local. There may be a typical "intention tremor" as well as loss of muscle tone, slow or scanning speech, nystagmus, loss of equilibrium and head tremor. These symptoms are usually masked at the outset and only become evident with the increased activity of the child during convalescence. Next come paraplegias and spinal cord syndromes. Loss of sensibility is present in most cases in the early stages, but this generally passes off during convalescence and is always less severe than the motor symptoms. The sphincters are frequently involved.

Mental disturbances as the chief feature are not uncommon, and initial delirium is present in almost all cases in which the nervous system is seriously affected, except in some cases of

acute ascending myelitis, and of some hemiplegias in which the onset is apoplectic. This early delirium is usually associated with high fever and is not more frequent or severe than in any other acute infectious disease. The commonest mental residuum of measles is reduction of intelligence. In the 125 cases abstracted by Ford mental defect was noted in 22. Change in personality, irritability, destructiveness, and a-social behaviour, such as are commonly found after epidemic encephalitis, are less common but are mentioned.

The pathological changes behind all these findings are those of a toxic-degenerative character rather than of an inflammatory process. There is characteristically a perivascular myelin destruction with collection of lipid waste products in phagocytes and even in the nervous tissues. There is also great congestion of the vessels with swelling and fatty changes in the vascular endothelium. Very little change can be made out in the axicylinders and little or no destruction of the nerve cells.

The prognosis for life is good. Only about 10 per cent of all measles patients die. About 65 per cent of those who survive show residual symptoms, there is weakness in 30 per cent, ataxia in 12 per cent, mental defect or personality change in 17 per cent, and epilepsy in 5 per cent.

Studio sulle modificazioni dei globuli bianchi nella anemia perniziosa progressiva in seguito alla terapia epatica. (A Study of the Modifications of the White Corpuscles in Progressive Pernicious Anæmia following Liver Therapy) GIANI, G., *Il Policlinico*, 1928, XXV, 2083.

GIANI in this article collects the data so far published in regard to the changes in the state of the blood in cases of pernicious anæmia which have been treated with liver extract after Whipple's method, together with his own observations. Important modifications in the red and white corpuscles are constantly observed. In 85 per cent of the cases the leucocytes are increased to the normal figure or even above it. As a rule the polymorphonuclear leucocytes are increased relatively and absolutely, while the lymphocytes are diminished. In not a few instances there is a noteworthy increase in the eosinophiles, figures such as 5, 7, 20, 25, and even 37 per cent have been recorded. The changes in question give one the impression that liver feeding promotes markedly the regeneration and functional activity of the bone marrow. They are, also, of prognostic import.

A. G. NICHOLLS

Value of Leucocyte Counts According to the Arneth Schilling Formula in Clinical Medicine Nicholas, F W, *Med Clin N A*, September, 1928

The Arneth-Schilling method of leucocyte count involves the classification of the leucocytes in a blood smear into embryonic, young, and mature types, according to the morphology and staining reactions of the nucleus and cytoplasm. By tabulating the percentage of the various forms at intervals during the course of an infection, an estimate may be made of the reaction of the hæmatopoietic system, and further evidence may be gathered for prognosis. A predominance of immature forms is said to indicate active stimulation of an efficient bone marrow. An alteration towards more mature polymorphonuclears and mononuclears is seen with recovery and in the presence of a grave infection with inadequate tissue response.

A series of cases are cited in which this method proved of value to the clinician.

Rotogravure Ink Dermatitis Oliver, E A, *J Am M Ass*, 1928, *xc*, 12

This is a report of 15 cases of dermatitis which were caused by the colouring matter used in the pictures of the rotogravure section of certain weekly papers. Dr Oliver's first experience with this type of dermatitis was in 1926, when a man of 66 consulted him for a severe dermatitis of the forehead and face. The history gave no clue beyond the fact that the dermatitis was always worse on Monday and Tuesday which suggested that the irritant responsible was met with over Sunday. It did not seem to be in his home environment, however, since spending Sunday at his office made no difference. It was finally concluded, therefore, that the only detail in which his life on Sundays differed from that on other days was the reading of the Sunday paper, which contained a comic section and a rotogravure section. He was advised to stop reading this paper and the dermatitis cleared up almost immediately afterwards. A year later experimental handling of the rotogravure section brought on a fresh attack of the dermatitis.

This case served as a clue in 14 others of a similar nature. In each instance it was clearly established that the dry colour used in the ink for the coloured section was the responsible factor.

The ink itself is made up of two components, a varnish, and a dry powder which gives the colour. The varnish is a solution of gelsomite (an asphalt) in naphtha and xylene. The powder added to this is a more complicated substance, consisting of a diazo dye, called para red, in which there is an irritating coal-tar product, paramitraniline. Cutaneous tests showed this

dry powder to be the irritant and not the varnish.

It is curious that no cases of dermatitis could be found amongst the employees of the paper or amongst those manufacturing the ink. In the discussion on the case it was pointed out that a patient might by judicious selection occupy himself with illustrated newspapers of this type all through the week and so develop continuous rather than periodical symptoms. The distribution on the body too may be variable, since the handling of the paper may permit of the ink being conveyed to different parts. One case of asthma due to the ink has been reported in New York.

SURGERY

Acute Thyroiditis Burhans, E C, *Surg, Gynec & Obst*, 1928, *lxv*, 478

Acute thyroiditis, with or without abscess formation, occurs commonly enough to warrant careful study. The blood supply of the thyroid is rich and the production of the thyroid hormone also tends to prevent infection of the thyroid, while the physiological changes occurring during puberty, menstruation, pregnancy, and acute infections, and the development of adenomata in the gland, tend to lower its resistance.

The disease may be acute or chronic, suppurative or non-suppurative. The acute inflammation may resolve or go on to suppuration and gangrene. When suppuration occurs, the suppurative lesions may consist of multiple milary abscesses or may be large pockets of pus involving one or both lobes. Chronic non-suppurative thyroiditis is seen in the neighbourhood of adenomata, causing a localized fibrosis of the interstitial tissue. Specific non-suppurative inflammations are caused by tuberculosis and syphilis, the former giving a large, hard, nodular tumour of rather rapid growth, the latter occurring in two forms first, the diffuse thyroiditis, and, second, gummatous Riedel's thyroiditis is of unknown etiology and is characterized by a marked fibrosis of the thyroid with adhesions to the adjacent structures and produces a gland so firm that it is often diagnosed as malignant.

There are numerous etiological factors in acute thyroiditis, trauma being one of them, but, aside from trauma, infection may occur in one of four ways (1) Through a persistent thyroglossal duct, (2) By direct extension from contiguous structures, (3) By lymphatic metastases, and (4) By blood stream metastases. The bacteria causing the infection are typhoid and paratyphoid bacilli, pneumococcus, streptococcus and staphylococcus.

Clinically, acute thyroiditis occurs suddenly

with swelling or tumour formation over the thyroid, producing pain in the neck which radiates to the mastoid region or the ear. There is tenderness over the gland and chills and fever may initiate the disease. Occasionally, there is coughing and hoarseness, due to oedema, swelling, and venous congestion of the laryngeal mucosa. Dyspnoea and dysphagia sometimes occur. As the disease progresses there is redness of the overlying skin, and in some of the cases toxic goitre symptoms develop.

The prognosis of the disease is excellent if it is recognized early. The treatment is that used in any acute inflammation, namely supportive and pain-relieving. If signs of suppuration develop, incision and drainage is the best treatment, and this is best accomplished through the ordinary collar incision, with retraction of the strap muscles followed by incision and tube-drainage.

R V B SMITH

Staphylococcal Suppurative Nephritis (Carbuncle of the Kidney) Dick, B M, *Brit J Surg*, 1928, xvi, 106

Some twenty-seven cases of carbuncle of the kidney are reported in the literature. The commonest portal of entry for infection into the circulation for the *S aureus* is a skin carbuncle, boils, or smaller multiple septic skin foci, but the portal of entry may be from a whitlow, a patch of eczema, or an acute osteomyelitis. The earliest age at which the disease has been known to occur is ten years. Only in one recorded case was the infection bilateral.

The symptoms come on gradually with malaise, headache, loss of appetite and elevation of temperature. The patient may have repeated rigors. Pain may be present at the onset, but often does not appear for a considerable time after the other symptoms. It is of a gnawing character, and is confined to the loin, and the side of the upper abdomen. As the disease progresses, the patient becomes extremely ill and sweats profusely. The bowels are as a rule very constipated. The abdominal muscles on the affected side show diminished respiratory movement, and, on palpation, there is defensive boarding, and a very ill-defined mass may be detected in the lumbar region. The leucocyte count is elevated, but, as a rule, microscopic examination of the urine is negative.

A valuable aid in the diagnosis is the history of a skin lesion. Pyelography should prove useful in determining whether a perinephric abscess has arisen from a renal carbuncle, and the discovery of a filling-defect in one or more calices would suggest an intrarenal origin of the abscess.

The treatment by nephrectomy is the most effective way of eradicating the disease, but, when the carbuncle is small, some cases have been treated by a localized resection of the involved

area of kidney, while some of the abscesses seen at operation have been only drained.

R V B SMITH

Auto-Transfusion, with Account of a Case. Denni, H B, and Kinsella, V J, *Brit M J*, 1928, ii, 568

The authors feel that auto-transfusion in surgical emergencies is a measure which has not received the notice it deserves. A case in which its value was demonstrated to them was as follows. A boy of twelve years had fallen and sustained fractures of the arms and skull, the abdomen was apparently uninjured and the patient had no symptoms in that region. A few hours later, however, he showed definite signs of severe intra-abdominal hæmorrhage, and his condition soon became desperate. The hæmorrhage had evidently been insidious in onset. He was taken to the operating-room and the abdomen was opened. A large quantity of fluid blood was found in the cavity and this was quickly ladled out and dropped into citrate solution. In the meanwhile Dr Kinsella opened a vein and reinfusion of the citrated blood from the abdomen was begun at once. The source of the bleeding was found to be a tear in the pedicle of the spleen. The bleeding appeared to stop as the transfusion proceeded, and in a short time the patient's condition showed marked improvement and he made a rapid and uneventful recovery.

It is suggested that reinfusion of patient's blood might be used more often than is done. Experience has shown that blood may thus be used even after lying in the abdomen for a considerable time. The method has been advocated in many conditions, such as ruptured ectopic gestation. It has also been used in splenectomy where in addition to his blood dyscrasia the patient suffers from much blood loss and shock. As soon as the spleen is removed it is held over a vessel of citrate solution and the blood squeezed out of it. This blood is then reinfused. Loyal Davis and Harvey Cushing have also found reinfusion useful in major cranial operations. Suction is used to remove the blood from the field of operation, and even towels and swabs may have their contents rung out.

It is stated that even citrate solution is not a necessary adjunct, as the blood has been given mixed with saline or even unmodified. But the citration is the most certain method of preventing clotting and it also permits of the injection being given slowly.

H E MACDERMOT

PATHOLOGY

On the Supposed Relationship between the Viruses of Herpes Febrilis and Vaccinia. Bedson, S P, and Bland, J O W, *Brit J Exper Path*, 1928, ix, 174

Gildemeister and Heitzberg (1925, 1927) have

produced evidence which, if correct, would indicate a close relationship between the viruses of herpes febrilis and vaccinia. Their work suggests that possibly the partial cross-protection which they claimed to have demonstrated, might have been overlooked by earlier workers. Further, they reported neutralization experiments with specific sera which supported their findings *in vitro*. The authors undertook to examine into this.

Their first series of experiments was carried out to elucidate the question of cross-immunity. Guinea-pigs were inoculated on the depilated hairy skin with herpes or vaccinia virus. After allowing a suitable interval for recovery from the primary infection they were tested for immunity with the same virus, and if the result of this test was satisfactory, the second virus was titrated on them. Control titrations were made on normal animals. The vaccinia virus was titrated on herpes-immune guinea-pigs, and herpes virus on vaccinia-immune animals. Little difference was found between the results of titration of herpes virus on normal and vaccinia-immune pigs and of vaccinia virus on normal and herpes-immune animals. Any slight differences that did occur might be explained as falling within the limits of experimental error.

A second set of experiments was carried on to investigate the question of cross neutralization. Anti-herpes serum, obtained by hyper-immunization of guinea-pigs, was diluted one-half with M/50 phosphate solution pH 7.6 and mixed with equal quantities of various dilutions of vaccine virus and after standing for one hour at room temperature the different mixtures were inoculated into pigs by scarification. Controls were made in which the anti-herpes serum was replaced by normal guinea-pig serum and also by the phosphate diluent.

Conversely, undiluted anti-vaccinia serum was mixed with equal parts of falling concentrations of herpes virus and inoculated by scarification after standing thirty minutes at room temperature. The herpes virus was a phosphate diffusate with a titre of 1/100. A control was made with normal rabbit serum. Also, vaccinia virus (titre 1/10,000), diluted 1/50, was mixed with falling concentrations of the serum and inoculated into guinea-pigs after standing one hour at room temperature.

Anti-vaccinia sera, undiluted, were mixed with an equal volume of herpes virus (titre 1/1000), 1/10, and inoculated. Controls were made with normal rabbit serum and phosphate. No inhibition of the vaccine virus occurred. The serum neutralization experiments fully confirmed the cross-protection experiments.

The authors think they have produced evidence to show that the viruses of vaccinia and herpes are unrelated.

A. G. NICHOLLS

THERAPEUTICS

Mercurochrome-220 Soluble Eyre, J, Notton, H. E. F. and Pope, Sir W. J., *Brit. M. J.* 1928, ii, 238.

This is a report of experimental analyses of various preparations of mercurochrome. The investigators had been impressed with the fact that intravenous injections of mercurochrome frequently caused symptoms of mercurial poisoning when given in 1 per cent strength, while comparable doses of 0.4 per cent were relatively free from this objection. It appeared therefore that certain samples of mercurochrome obtained in the open market were more toxic than others and examination of the various products was accordingly undertaken.

First of all, the chemical constitution was analyzed and a surprising diversity of composition was found to exist amongst the four samples examined, the differences being caused by varying percentages of contaminating substances. These various samples were then tested on rabbits and the conclusion reached was that the toxicity appeared to bear a direct relationship to the purity of composition.

Some clinical observations were also carried out, the sample tested being that which conformed most nearly to the theoretical constitution of the drug. The general impression gained during the employment of this particular sample was that its therapeutic activity was similar to other types of mercurochrome used in previous years, but that it was distinctly less toxic.

The experiments and observations all point to the fact that the nearer mercurochrome approximates in its analytical results to its known chemical constitution, the better the preparation as regards therapeutic efficiency and low toxicity.

H. E. MACDERMOT

The Therapeutic Action of Plasmoquinine and Plasmoquinine Compound in Malaria Manson-Bahr, P., *Lancet*, 1928, ii, 496.

During three hundred years quinine has been used as an anti-malarial specific with no radical changes in its therapy or results. It is well known that the parasite, especially that of the benign tertian type, may not be extirpated but only held in check by repeated courses of quinine over a period of years. Other cinchona compounds have proved no better. Moreover, definite individual intolerance to quinine exists and though intramuscular and intravenous administration may be used in some cases this is not always practicable or safe and an alternative drug has long been desired.

Plasmoquinine—a synthetic derivative of quinine (alkylaminomethoxyquinoline) was used in tests against bad malaria (*Plasmodium præcox*). It was found to be sixty times as potent as quinine, especially acting upon the

sexual stages (gametocytes) towards which quinine is almost inert, but having less action on the sub-tertian types. In human malaria a dose of 0.06 gm (gr 1) daily was found sufficient. Large doses cause cyanosis, abdominal pain, and other toxic effects. The spleen is reduced in size with great rapidity. Only one-tenth of the daily dose is excreted in the urine, and courses of one week each, with five days rest between courses, are necessary to allow elimination and avoid toxicity. It was later found that the addition of a small amount of quinine sulphate increased the potency to sub-tertian types and prevented toxic manifestations. This mixture is called plasmoquinine compound, and used in tablets. The formula is plasmoquinine, 0.01 gm (gr 1/6), and quinine sulphate, 0.125 gm (gr 11).

The dosage is important. The following routine is suggested for benign tertian or quartan for one week, 2 tablets of plasmoquinine compound three times daily, four more courses, with 4-day intervals, giving 12 tablets daily. For sub-tertian types for five days, 2 tablets thrice daily, with 4 days' interval, five more courses of 5 days, with 4 days' intervals.

Disintegration of the crescents is seen after 8 tablets of plasmoquinine compound, when they may persist one month under quinine.

Eighteen cases of the benign tertian type are cited. All showed rapid improvement with contraction of spleen, even two cases which were intolerant to quinine. Eleven cases of the sub-tertian type were less satisfactory but the results were as good as with quinine. One case of the quartan type, with relapses for four years, has had none since a course of plasmoquinine compound.

It is concluded that there are not sufficient grounds for stating that plasmoquinine compound will replace quinine, but it offers an efficient substitute in patients with an intolerance, being tasteless, easily tolerated, and showing a negligible effect on digestion.

J. B. ROSS

Quel doit-êtré Actuellement le Traitement des Cancer du Sein (What is the Proper Treatment of Cancers of the Breast?) Bérard, L., *Strasbourg Medical*, 1927, vii, 116

This author first comments on the considerable variations in malignity that characterize the various tumours of the breast. Those in which the cells and their arrangement are irregular, without secretory functions, with numerous and irregular mitoses, and with marked hyperchromatism of their nuclei, are much more malignant than, say, the adenocarcinomata, in which these characters are not nearly so marked. The malignity is also more marked in the case of cancers affecting young women, and when the growth appears during

pregnancy, or *post partum*. Before one can lay down precise rules for therapy in cases of cancer of the breast it is necessary to know how these various types react to the therapeutic agent. Actually, the probability of cure depends above all on the early institution of treatment. If we can get the cases within two months of the appearance of the growth we can expect that the cures, after five years, will exceed 75 per cent. Treatment is directed to the destruction *in loco* of all the neoplastic cells in the tumours and in the lymphatic districts of the corresponding side of the thorax. Surgery gives, on an average, 35 per cent of cures, observed after two years, and 25 per cent, after five years. It is always of advantage to precede and follow operation by methodical radiotherapy. One should irradiate the whole antero-lateral region of the hemithorax, divided into five fields, mammary, perimammary, axillary and subclavicular, with moderate intensities (140 to 180 thousand volts), with half a centimetre of copper as a filter, at repeated sittings, the length and frequency of which will depend on the degree of resistance of the patient.

Preliminary radiotherapy is valuable for sterilization of the tumour and the lymphatics. Operation produces traumatic lesions of the cells of the region which hampers their means of defence and the useful effects of radiation. Recurrences should be treated like the primary lesions. First of all, x-ray or radium therapy at a distance, then surgical removal of all that can be extirpated without great destruction of the part.

Inoperable tumours and their metastases can be greatly benefited by the use of these physical agents, which are able notably to prolong life, lessen suffering, and sometimes make palliative operations possible.

A. G. NICHOLLS

Ueber die Prophylaxe der Varizellen (On the Prevention of Varicella). v. Keszmarzky, K., *Arch f. Kinderheilkunde*, 1928, lxxv, 1

In the Children's Clinic of the Royal Hungarian Elizabeth University in Pesth they have been endeavouring to obtain protection against varicella by the use of blood taken within the first thirty-six hours after the appearance of the rash from patients suffering from that disease. The freshly drawn blood is mixed with one-tenth its volume of a 5 per cent citrate solution, and 0.1 c.c. is injected intracutaneously. Of 51 children of all ages from two months to fourteen years, who had been exposed to infection, 50 escaped (98 per cent).

The procedure is simple, efficacious, and not followed by unpleasant or dangerous consequences. That the infection of varicella is not transmitted from the ill to the well by this

treatment is thought by the author to be due to the dilution of the blood or to the weakening of the virus contained in it. Possibly, though this is not suggested, it may be due to the fact that an exceedingly small amount of blood is injected, and this into the skin where absorption must be slow, giving time for the local defensive mechanism to get into action.

The duration of the immunity so produced is unknown. The author in one case observed the development of what appeared to be a varicellous herpes zoster eight months after injection.

The method is, of course, particularly useful in cases where children are known to have been exposed to infection in institutions, or where one member of a family has been attacked by the disease.

A. G. NICHOLLS

Die rohe und gerostete Kaffeebohne in der Therapie (Raw and Roasted Coffee-beans in Therapeutics) Petoe, A, *Die Medizinische Welt*, 1928, vii

After the continued administration of the powdered green coffee bean an increase in the calcium content of the blood is observed, due probably to the citric acid in the bean. The blood picture in anemia is favourably influenced by green coffee.

The green coffee is administered either as a powder in doses of 2 to 3 grams, or as a maceration prepared as follows. One hundred and fifty grams of green coffee are broken up in a mortar or ground in a mill, covered with 500 cc of water, and allowed to stand over night. In the morning the mixture is filtered and one to three teaspoonfuls of this extract form a dose.

The roasted coffee bean can be given as a powder in half gram doses, or the patient can be instructed to chew four of the beans. The author states that when a 'cold' is impending the prodromal symptoms can be cut short by three teaspoonfuls of the maceration taken three times in the day. In the case of acute rheumatic fever the local lesions and the temperature are favourably influenced. Here, the patient is advised to drink a tumbler of the maceration in the morning on an empty stomach. In chronic articular rheumatism 0.5 gm of the pulverized raw coffee is ordered six times a day. The unpleasant symptoms that are so often attributed to the weather are speedily relieved. In the nausea and vomiting of acidosis and vagus irritation coffee seems to be almost specific. In cases of the vomiting of pregnancy and in train- and sea-sickness the author advises the sufferer to chew slowly three or four roasted coffee beans.

Obituaries

Dr Henry Richard Smith. After a short illness of three days only, one of the best known and most highly respected physicians of Edmonton died on October 24th, 1928, from erysipelas complicated with streptococcal encephalitis. Still in the prime of life, of vigorous constitution and powerful physique, his sudden death came as a great surprise and shock to his medical confrères as well as to the whole community.

Born in New Hamburg, Ont., on September 11, 1873, of English parentage, Dr Smith obtained his preliminary education at Woodstock Collegiate Institute and Albert College at Belleville, after which he studied medicine at Trinity University, Toronto, graduating in the class of 1899. The next two years were spent in post graduate study at Edinburgh and London, and as house surgeon in Toronto General Hospital. In 1901 he came to Alberta and practised for a year and a half at Star, removing to Edmonton where he has resided continuously for twenty five years, taking an active part in the life of the community. In politics he was a staunch Conservative, at one time being elected President of the Conservative Association. In civic affairs he took a close interest, being elected a member of the City Council for the years 1913 and 1914. Always interested in medical matters, he took an active part in the local medical association and became President of the Alberta Medical Association in 1910. A member of the McDougall Church, he had been closely associated with the work of Alberta College, having been Chairman of the Board since 1913 and of the building committee. To his untiring industry and energy, not a little of the success which has attended this fine teaching institution is due. Since 1921 Dr Smith held the position of Medical Superintendent of the City Hospital

Dr H. R. Smith

Board, having charge of the Royal Alexandra and Isolation Hospitals.

Under his careful and tactful management, combined with rare executive ability, these hospitals have reached the highest standard of efficiency and service, while at the same time the annual deficits have gradually been reduced till at the present time the institutions are practically self supporting.

In 1901 Dr Smith married Martha Doyle, a daughter of John Doyle, of Elora, Ont. She died in 1903, leaving one daughter who is now Mrs. Fred. Jackson, of Clover Bar district. In 1906 Dr Smith married Mabel Rife, a daughter of David Rife, of Hespeler, Ont., who survives him with one son and two daughters, Howard and Constance, who are students of

Alberta University, and Margaret at home. Two sisters, Mrs Mabel E Davis and Mrs Eliza Smith, of Toronto, and two brothers, F C Smith, of Lamont, Alta, and J H Smith, C.E., of Colombia, South America, also survive. T H WHITEHEAD

Dr Hugh Ross passed away at the home of his son, Mr Neil Reginald Ross, in Boston, Mass., on Saturday, November 3rd. The body was taken to Clifford on Monday, November 5th, and interment was made in Clifford cemetery.

Dr Ross was born on November 11th, 1845, at Brucefield. His father, Neil Ross, was the first settler in that part of Huron Tract, and his elder brother, Donald Ross, was the first white child born between London and Goderich. Dr Ross was educated at the rural school near Brucefield, and at the grammar school

Dr. Hugh Ross

in Clinton. After teaching school for two years, he attended Trinity College, Toronto, from which he graduated with honours in 1872. In November, 1873, he married Mary Bailey, of Toronto, who predeceased him in May, 1912. He spent fifty-five years in the practice of medicine, having gone to Clifford in 1881 and remained there in active practice until 1927 when he sold his practice to Dr A. F. Thaler.

He leaves to mourn his loss one son, Neil Reginald, four daughters, Mesdames Guaggenti and Creighton, the Misses Caroline and Margaret, and one sister, Mrs. Macdonald, of London, widow of the late Dr Peter Macdonald of Wingham. A. F. THALER

Dr Eugène Latreille. One of the best known Montreal practitioners died on November 9, 1928, in the person of Dr Eugène Latreille, Professor of Pathological Anatomy at the University of Montreal, one of the consulting physicians of the Hôtel Dieu Hospital, Officier d'Académie (France), member of the Federal Medical Bureau, late President of the Société Médicale.

Dr Latreille died suddenly in his office, 3478 St Denis Street, shortly after six o'clock at night. He had been ill for three years from high blood pressure and cerebral hemorrhage, but that had not prevented him from giving consultations at his home. A few minutes before his death he had just dismissed some patients.

He was forty-nine years of age. Born in Montreal, he studied at Laval, practised in the local hospitals and

then went to Paris, where he entered the Faculty of Medicine as a student and was received a Doctor of the Faculty of Paris after the regular curriculum. On his return to Montreal, he built up an extensive practice.

He was appointed to the Chair of Pathological Anatomy in the Université de Montreal in the year 1910, following the resignation of Prof E St Jacques, and he discharged the activities of this post with great zeal and efficiency until 1916, when his failing health led to his replacement by the distinguished scientist Professor Masson, late of Strassbourg.

Dr Latreille was an active contributor to the proceedings of the Société Médicale de Montreal and prominent in the editorial management of *L'Union Médicale*, the local organ of the French profession in Montreal. By his effort also he did much to build up and reorganize the pathological museum of the Université de Montreal after its damage by fire in the year 1916, and in this connection he maintained intimate and fruitful relations with the management of the Pathological Museum of McGill University and the Exchange Department of the International Association of Medical Museums.

Dr Latreille is survived by his widow, formerly Miss Berthe Lamontagne, Madeleine, a daughter, Mrs D C Cartier, Mrs Alphonse Lamy and Miss Aldea Latreille, sisters, and Dr Aime Lamontagne, a brother-in-law.

AN APPRECIATION

Three years ago Latreille was suddenly seized with an attack, which he himself was able to diagnose as cerebral hemorrhage. At that tragic moment disappeared one of the finest figures in the medical profession of Canada. His life since was a brave struggle against the progression of his malady. Now the dramatic contest is over and Latreille is no more.

Always interested in music, those who knew him at the university will remember with what mastery he could conduct an orchestra or a chorale. If he had pursued his bent he would have progressed as far as he eventually did in his chosen profession, medicine.

While pursuing his studies at Paris he developed a talent for pathological anatomy and clinical medicine which became a veritable passion with him. His thesis for his doctorate "*Contribution à l'étude des modifications de la surrenale*", Paris, 1907, proved that he did not fear laborious tasks, on the contrary, complicated situations always interested him, he looked for the rare cases, the difficult diagnoses, he had scientific curiosity. He was, in fact, an artist in medicine as he would have been in music.

Teaching brought the greatest satisfaction to Latreille. He enjoyed it, not only for the pleasure of communicating his knowledge to his enquiring pupils, but because it called for a sort of intellectual gymnastics in compelling careful preparation of his theme.

Of humble origin, like most Canadians, for very few can claim descent from the loins of Jupiter, Latreille was essentially the aristocrat. Yet, those who know him best will recall that he could unbend and give himself with abandon to the most animated discussion on many out of the way topics.

My old friend and comrade carries with him the unanimous tribute of admiration from all who had the privilege of knowing him.

The Université de Montréal will cite him as an example to future generations, the Hôtel Dieu will never forget the void created by his departure, and his pupils will long remember his authoritative lectures, the Société Médicale de Montréal will often recall the numerous brilliant communications which he made to it, and the Editorial Board of *L'Union Médicale* will realize that they have lost a colleague whose writings were always remarkable for their originality.

Latreille did much to elevate the character of our budding Canadian medical science. P. Z. RHEAUME

Dr Raoul Masson One week after the sudden death of Professor Latreille, the faculty of medicine of the University of Montreal lost another of its members in the person of Dr Raoul Masson, who died suddenly at the close of a meeting of the medical board of Ste Justine Hospital, of which he was chairman. Death was due to heart failure.

Dr Raoul Masson was born in Montreal, February 6, 1875, the son of Joseph Edouard Masson, of Lake Masson, St Marguerite, Que. He studied at Terrebonne and St Mary's Colleges, then at Montreal College and at Laval University of Montreal. He was admitted to the practice of medicine in 1902, with honours, and went to Europe, where he specialized in the study and treatment of the diseases of childhood.

The late Dr Masson was Professor of Pædiatrics at the University of Montreal, professor of child hygiene at the provincial schools of domestic science, governor of Notre Dame and Ste Justine Hospitals, of which last named hospital he was one of the founders, some years ago. He always took an active part in the fight against infant mortality, and was a firm believer in the parochial free milk stations for indigent mothers.

One of the administrators of the Masson Estate, he was also vice president of the Société Médicale du Mont réal, member of the Cercle Universitaire, the National A.A.A., the Kiamika Hunting and Fishing Club, the St Denis Club, and the officer's mess of the 65th Regiment, C.M.R. Mrs Masson, having predeceased her husband in April last, he is survived by one son, Léon Masson, and by two brothers, Leopold Masson, of Montreal, and Leon Masson, of Terrebonne.

AN APPRECIATION

By the most untimely death, on November 14th, of Dr Raoul Masson, who was Professor of Pædiatrics at the University of Montreal, and of Clinical Medicine at Ste Justine's Hospital, the medical faculty has lost one of its most distinguished members.

Dr Masson will be remembered not only by the medical profession but also by the public, who recognized in him a most remarkable personality. He was a leader, and a very active one, in the fight against infantile mortality, and only in the afternoon before his death he had received about forty mothers with their children, at the Baby Clinic of the Sacred Heart Parish, leaving the clinic almost exhausted a few hours before his death.

Of a most amiable character, Dr Masson was well liked by all those who had the pleasure of knowing him, both professionally and socially, and was recognized as a guiding spirit by all students attending his clinics.

His loss is most regretted and will be keenly felt.
GASTON LAPIERRE

Michael Thomas Sullivan, M.D., C.M. The sudden and unexpected passing of Dr M. T. Sullivan of Glace Bay, which took place at the Halifax Hotel on the morning of November 18, 1928, came as a shock to all members of the Medical Society of Nova Scotia. For more than 25 years he has been almost our most constant attendant at annual meetings and only the day before his death he expressed to the secretary of the Society his great regret that he was unable to be with us at our 75th anniversary meeting. In 1920 he was elected a vice president of our Provincial Society and he was its president in 1921 when the renaissance of the Medical Society of Nova Scotia took place. Our present day organization owes much to the wisdom and energy of Dr "M.T.", as he was familiarly called.

Dr Sullivan was born in Glace Bay on March 13, 1874, a son of Michael and Susan (Lott) Sullivan, formerly of Sydney. He received his education at the common schools of Glace Bay and then entered St Francis Xavier College. He graduated from the medi-

cal faculty of McGill University in 1901 and at once started practice in his home town. To few men is it permitted to make good as we use the expression, to the extent that did Dr Sullivan. At that time certain men stood very high in the esteem of that community. Drs McKay and McKee had been the strong men in the profession and very shortly Dr Sullivan was called upon to fill their places. That he did this with honour to the profession, with credit to the hospital in which he did his best work, and to himself, is vouched for by any one who knows anything of Glace Bay.

It was no small task that was set before this young medico when two great men passed along and handed him the torch. Ability, knowledge, personality, confidence, honesty, and the faculty of seeing weak points and how they could be overcome, enabled him to become the presiding genius, if we may use the expression, of St Joseph's Hospital. Just here it is only fair to note that much of Dr Sullivan's influence in both town and hospital matters was due to the wise and kindly counsel of Mrs Sullivan, whose efforts for community welfare in Glace Bay are recognized by all.

We are flooded with critics and knowers but "Mike Sullivan" always told you how you should do the job he brought under fire. He never was a destroyer, he was always trying to build up. Perhaps here lies the secret of the great influence such men as Dr Sullivan have in their respective communities. Certainly no citizen of Glace Bay was any more influential than he. He was always building up, whether in his own professional work, in the town or county, in St Joseph's Hospital, the medical societies, the Board of Trade or the activities of his Church, he was always looking forward to bigger and better things.

Dr Sullivan was an executive member of the Associated Boards of Trade of Cape Breton Island and a member of the Executive of the Cape Breton Tourist Association. He belonged to the Glace Bay Council of the Knights of Columbus, the Catholic Mutual Benefit Association and the Ancient Order of Hibernians. He was married on June 11, 1902, to Miss C. McLean of Antigonish. He is survived by Mrs Sullivan and their six children.

His funeral took place in St John's Church, New Aberdeen, on Wednesday, November 21st, conducted by Dr H. P. McPherson, vicar general of the Diocese of Antigonish, representing His Lordship Bishop Morrison. The Medical Society of Nova Scotia extended to Mrs. Sullivan and family sincere sympathy and sent floral offerings as did also the local Branch Society.

The Halifax press published several fitting tributes from prominent persons. From these we may quote the following by Dr S. R. Johnston, President of the Halifax Medical Society:

"In spite of the long years of practice, during which he soon became recognized as one of the outstanding surgeons in the province he always found time, through personal sacrifice, to take part in educational and other voluntary medical activities. He was a member of the American College of Surgeons and, in this connection, did much to further the scheme for hospital standardization, the value of which is now so universally recognized. It is only little more than a year ago since he read, before the Halifax Medical Society, a valuable paper on "The Surgery of 25 Years in a Mining Community"—a paper filled with keen observations drawn from these long years of hard, laborious work under trying circumstances.

Regarding his sterling qualities as a man, much might be said. The beautiful words of Browning would appear fitting:

"One who never turned his back, but marched, breast forward,

Never doubted clouds would break,
Never dreamed, though right were worsted, wrong
would triumph.

Dead, we fall to rise, are baffled, to fight better,
Sleep, to wake' "

His passing makes a gap in the ranks of the medical profession in this province which will not soon be filled. The heartfelt sympathy of the Halifax Medical Society goes out to his sorrowing widow and family.

S L WALKER

Dr Samuel McMurrich McLay died in Woodstock on November 2, 1928. A graduate of Toronto University in 1910, Dr McLay had been intimately connected with the professional activities of Woodstock for nearly twenty years, and was a practitioner of exceptional merit. With the outbreak of war Dr McLay went overseas and gave freely of his services for the duration of the conflict. Returning to Woodstock, he resumed his practice, and soon became interested in the many problems of education and civic welfare. He had been Chairman of the Board of Education for some years, only slackening up in his activities when a trying illness of many months' duration had made this necessary.

Rev William T Bruce, M.D., Truro, N.S. At the advanced age of 87 years there passed away, after only a week's illness, a stalwart of the Presbyterian Church that the younger generation of medical men had for gotten. Dr Bruce was born at Middle Musquodoboit, graduated in Arts from Dalhousie, in Theology from Pine Hill, and in Medicine from Edinburgh, for the purpose of becoming a medical missionary. Poor health forced him to abandon this objective and he devoted many years of service to many churches in Nova Scotia, where he was greatly beloved. His health forced him again, some twenty years ago, to retire from active preaching, and he has lived a quiet life in Truro since that time. His wife predeceased him in 1918. Six sons and two daughters survive.

Dr Archibald A Chisholm, Manuels, Nfld. The death occurred on October 7th, of Dr A. A. Chisholm, a native of Antigonish County, N.S., a son of the late Mr and Mrs Archibald Chisholm of Beaulieu. He graduated from the University of Baltimore in 1897, and was sixty-two years of age. He is survived by his wife, formerly Miss Margaret MacNeil, sister of Archbishop MacNeil of Toronto, and one son and daughter. The son, William, is now a student at St. Francis Xavier University.

Dr R. Courchesne. Following an attack of pneumonia, Dr Robert Courchesne, died at his home, on October 24th, in his thirty-fourth year. Dr Courchesne was born in St. Francois du Lac, and had practised in Montreal for five years. He was a graduate of St. Mary's College and the University of Montreal.

Dr N. A. Davis, of Madawaska, died late in September, 1928. He was a graduate of Queen's University

in 1898, and had practised in Madawaska for thirty years.

Dr J. H. Duncan died at Chatham, on September 22, 1928. He was M.B. of the old Toronto School in 1881. Dr Duncan had practised continuously in Chatham for forty-seven years, and was well known as a hard working general practitioner.

Dr Margaret Gordon, one of the best known of the medical women in the country, died on September 22, 1928. She graduated at Trinity in 1898 and was associated with the Women's Medical College up to the time of its absorption by the University of Toronto. A keen worker, one of the first women to see that women must fight for suffrage rights, and one of the first to lead in that fight, Dr Gordon was always the centre of any movement which had to do with the betterment of woman's condition.

Dr Peter L. Graham, one of the oldest of the medical profession in the Province of Ontario, died at Lobo, on November 4, 1928. He was a graduate of Trinity College, Toronto, in 1877. Dr Graham practised at Lobo for more than fifty years and was known as a fine type of the old physician.

Douglas B. Kennedy, M.C., M.D., D.P.H., died in the Toronto General Hospital on September 25th. He was born in Pembroke, Ont., and graduated in Medicine at Queen's University in 1902. After leaving college he served as an interne in the Water Street Hospital, Ottawa, for a year, and was then appointed ship's surgeon by the Elder Dempster Line. In 1907 he was engaged as physician in connection with the construction work of the Grand Trunk Pacific Railway. In 1913 he was on the staff of the Rotunda Hospital, Belfast.

During the war he was attached to the Sixth Field Ambulance, and was mentioned in despatches several times, being awarded the Military Cross in 1917.

After demobilization he returned to his former occupation as medical officer on various pieces of construction work. He received the Diploma of Public Health in 1923 from Toronto University. Dr Kennedy was a brilliant diagnostician and an able industrial physician.

Dr James Palmer Peake died suddenly at his late residence, Ashern, Manitoba, on November 11th, in his sixty-second year. Dr Peake was a native of New Brunswick, and graduated in 1896 from McGill University. His wife, who predeceased him, was a daughter of John Wilmot, Esq., and granddaughter of the late Hon. R. D. Wilmot, formerly Lieutenant Governor of New Brunswick. Dr Peake served in the late war as medical officer of the 78th battalion (Winnipeg Grenadiers), winning the Military Cross. He is survived by two daughters. The funeral took place on November 17th to Brookside Cemetery.

We can increase our powers of observation by training and practice, and we can extend their range by means of special instruments and methods. We can increase our knowledge by study and experience, but can we improve our powers of judgment? I greatly

doubt it. Judgment seems to be an inborn faculty, the result of a union of mind and character, which a man either has or has not, and it is almost as difficult to increase it as it is to add a cubit to his stature—Robert Hutchison, *Brit. M. J.*, 1928.

News Items

GREAT BRITAIN

The Medical Society of London

At the opening meeting of the Medical Society of London it was announced by the Hon Treasurer that the famous John Ward Diary had been sold for £10,000. Of this sum £9,000, he said, had been invested, the remaining £1,000 going to the improvement of the Library.

The National Association for the Prevention of Tuberculosis

The fourteenth annual conference of the National Association for the Prevention of Tuberculosis was held on October 15th and 16th, in the Great Hall of the British Medical Association House, Tavistock square, London. Sir Arthur Stanley, as Chairman of the Council, formally opened the conference at 10 a.m. on Monday, when Dr R. C. Ferguson, of Saskatchewan, introduced the subject of the occurrence of tuberculosis among primitive peoples. He was followed by Colonel J. J. Vassal, M.D., ex-director of health of French Equatorial Africa, and by Prof. S. Lyle Cummins, principal medical officer of the Welsh National Memorial Association. On Tuesday Sir Robert Philip introduced the second subject, being the principles underlying a scheme of anti-tuberculosis measures in any country. He was followed by Dr Howard Holbrook, of Hamilton, Canada, and Dr G. Lissant Cox, central tuberculosis officer for Lancashire. The discussion was continued on the afternoon of each day.

Welsh National Medical School

The dispute between the authorities of this School and the Cardiff Royal Infirmary, where the students have hitherto done their clinical work, appears to be reaching a climax. Public opinion in South Wales is crystallizing on the side of the authorities of the medical school, whose efforts to provide adequate instruction for students in their final years have been nullified by the refusal of certain members of the staff to co-operate. Lord Aberdare, who has been the treasurer of the hospital for several years and a most generous subscriber to its funds, has resigned this post, giving the following

reason: "The recent decision of the Council not to co-operate with the medical school is so contrary to all I expected of them that I feel bound to take this step." He has refused to reconsider his resignation and has suggested that the matter in dispute should be referred to Sir John Eldon Banks. At a meeting of the Cardiff City Council, held on October 8th, Alderman H. M. Thompson asked the chairman of the Finance Committee when the committee were going to recommend to the City Council the withdrawal of the £2,000 subscription granted to the Cardiff Royal Infirmary, in view of the action of the executive body of that institution in arbitrarily withdrawing facilities necessary for the medical education of Welsh students. It seems probable that the embarrassments of this unfortunate school may shortly be relieved.

Sir Charles Tomes

The death, on October 23rd last, of Sir Charles Tomes, at the age of 83, recalls the career of one who did much to raise odontology to its present position among the medical sciences. His work, however, was largely a development of what had been begun by his no less distinguished father, Sir John Tomes, of whom it has been said that "he began to practise dentistry when it was a trade, and left it a well equipped profession, he showed that a dentist is capable of the highest kind of scientific work—that of scientific observation."

After a brilliant career at Oxford where he placed himself in the first class in the School of Natural Science, Sir Charles Tomes entered as a medical student at Middlesex Hospital, where his father, who was then on the staff as surgeon dentist, had studied before him. His studies on the development and structure of teeth were largely responsible for his being elected F.R.S. at the early age of thirty-two. Twenty years later his dental researches were recognized by election to the Fellowship of the Royal College of Surgeons of England.

The many tributes paid to him show him to have been a man not only of high scientific capacities, but one who also possessed and developed to a high degree an artistic sense and a keen interest in a wide variety of subjects.

PRINCE EDWARD ISLAND

Drs W. J. MacMillan, Charlottetown, and E. T. Tanton, Summerside, attended the annual meeting of the Medical Council of Canada, held on September 5th at Ottawa, as representatives of the Prince Edward Island Medical Council.

The Trustees of the Prince County Hospital, Summerside, have purchased for a nurses' home, the property across the street from the hospital, lately owned by Mr. F. A. Johnston. This is a very nice property with splendid grounds and will make an ideal nurses' home. The purchasing of this property will also release a number of private rooms for the use of patients, thus increasing the accommodation of the hospital.

The Extra Mural Post Graduate lectures, under the auspices of the Canadian Medical Association,

which were held at Charlottetown in the City Hospital on September 26th, were well attended. The lecturers were Dr. H. B. Atlee, gynaecologist and Dr. F. B. Mack, urologist, both of the teaching staff of Dalhousie Medical School, Halifax. The lectures were well presented and were essentially practical.

At the morning session Dr. Atlee took up the subject of abortion, which he treated in a very able manner. Dr. Mack dealt with urological symptoms in general and the importance of investigating these symptoms properly.

At the afternoon session Dr. Atlee discussed "Pelvic infection", and went into the treatment very thoroughly. Dr. Mack dealt with "Hæmaturia and pyuria" in an exhaustive manner. The lectures were illustrated by lantern slides.

The thanks of the meeting were conveyed to the lecturers by the Chairman, Dr. S. R. Jenkins.

J. A. MACPHEE

NOVA SCOTIA

A Medical Week at Halifax

From the fifteenth to the twentieth of October, the medical profession of Nova Scotia foregathered at Halifax for the seventy fifth annual meeting of the Provincial Medical Society. The meeting was arranged to synchronize with the "refresher course" which the medical faculty of Dalhousie University provides every autumn, and one day of the week was set aside to celebrate the sixtieth anniversary of the birth of the faculty. The most harmonious co-operation between Society and University, coupled with the practical assistance of the Canadian Medical Association, combined to make the week an unqualified success and to provide several unusual and rather interesting features. Through the good offices of the Canadian Medical Association the profession of nearly every province in the Dominion was represented, while each Canadian Medical School, with but one exception, had its representatives in attendance at the distinctively Dalhousie functions.

The general arrangement of the program was similar to the refresher course of past years, the mornings being given up to clinics and the afternoons to formal lectures. At the afternoon lectures, however, Dr L R Morse, President of the Medical Society of Nova Scotia, occupied the chair. Most of the clinics were by members of the Dalhousie faculty, but, on the other hand, most of the lectures were by visiting physicians, including Dr M G Archibald, of British Columbia, Dr George R Johnson, of Alberta, Dr William Boyd, of Manitoba, Drs J W Crane and Alexander Primrose, of Ontario and Dr W W Chipman, of Quebec.

At the dinner of the Medical Society, Drs Primrose and Routley conveyed the greetings of the Canadian Medical Association, while several provincial societies were officially represented as follows: British Columbia by Dr Archibald, Alberta by Dr Johnson, Manitoba by Dr Boyd, Ontario by Dr E A McQuade, Quebec by Dr Chipman, New Brunswick by Dr J V Anglin, and Prince Edward Island by Dr H D Johnston. Each of these extended felicitations on behalf of his Society, as did the representative of each of a number of the branches of the Nova Scotia society.

On Dalhousie Day, after the morning clinics, all in attendance were entertained at luncheon by the governors of the University. In the afternoon a ceremony of particular interest took place at the Dalhousie Health Centre when honorary degrees were conferred on Dr Finlay MacMillan, the only surviving member of the first class of graduates (1872), and upon Dr Alexander Primrose and Dr W W Chipman, both natives of Nova Scotia. Dr George H Murphy, on behalf of the Halifax branch of the Medical Society, presented a tablet in memory of the original faculty. For the Cape Breton branch, Dr J C Morrison asked the University to be custodian of enlarged photographs of Lt Col R. C. McLeod, Lt Col T Howard MacDonald, Major Walter MacLean and Major Kenneth A MacCuish, members of the Cape Breton profession who gave their lives in the Great War. To the university, various donors presented enlarged photographs of former members of the medical faculty, and a bust of Sir Charles Tupper, who was actively identified with the establishment of the school. In the evening, a Dalhousie medical dinner was held when, besides local oratory, short congratulatory speeches were heard from Major General Foster, (representing the University of Alberta), Dr J J Guerin, (University of Montreal), Dr W W Chipman, (McGill University), Dr J V Anglin, (Queen's University), Dr Alexander Primrose, (University of Toronto), Dr J W Crane, (University of Western Ontario), Dr William Boyd, (University of Manitoba). Laval University telegraphed regrets at

inability to send a representative, but sent cordial greetings.

The tablet referred to above bears the following inscription:

IN MEMORY OF THE FOUNDERS OF THE
FACULTY OF MEDICINE
OF DALHOUSIE UNIVERSITY
1868

W J Almon, M.D., Pres	Edward Farrell, M.D.
A P Reid, M.D., Dean	A H Woodall, M.D.
A G Hattie, M.D.	J D Ross, M.D.
G Lawson, Ph.D., LL.D.	T R Almon, M.D.

Rev James Ross, Principal, Ex officio
"THEY BUILT BETTER THAN THEY KNEW"
Placed by the Halifax Branch of the
Medical Society of Nova Scotia, 1928

The clinics were held mostly at the Victoria General Hospital, though the Children's and the Grace Maternity Hospitals each shared. Except on Dalhousie Day the afternoon lectures were given at the new Lord Nelson Hotel, which was completed just in time to permit of its utilization as headquarters for the Medical Society and which was reserved for that purpose. This fine hostelry was, in effect, a medical club for the week.

In addition to the functions already mentioned, a complimentary luncheon to honorary members deserves special notice. While the number of honorary members who could attend was small, the occasion was notable on account of the presence of Dr A J Cowie, who, though upwards of ninety three years of age, made a vigorous and interesting speech.

Numerous minor functions were arranged for the wives and daughters of visiting doctors, and on Friday evening both sexes took part in a very enjoyable dinner dance.

The showing of the film illustrating the action of radium on the animal cell, arranged by courtesy of Dr Routley for the Canadian Medical Association, attracted much favourable comment. This was thrown open to the public, and was attended by large numbers of the laity.

Tenders are asked for the erection of a new wing to the Payzant Memorial Hospital, Windsor.

At the annual meeting of the Associated Boards of Trade of Cape Breton, held early in October, Dr M T Sullivan, Glace Bay, was elected President, and Dr Nat MacDonald, Sydney Mines, Vice president.

The Halifax Society of McGill Graduates tendered a complimentary luncheon to Mr E W Beatty, Chancellor of the University, at the Lord Nelson Hotel on October 23rd. Dr A E Donll is President, and Dr J C Acker is Secretary of the Society.

An addition is to be made to the Soldiers' Memorial Hospital, Middleton, to release room in the present structure for the accommodation of an x-ray plant which has been presented to the hospital by Drs J A Sponaglo and L R Morse.

A bulletin of the American College of Surgeons, recently issued, announces that eleven of the twelve hospitals in Nova Scotia, which have a capacity of fifty or more patients, have been "fully approved."

These are the Highland View Hospital, Amherst, St Martha's Hospital Antigonish, Glace Bay General and St Joseph's Hospitals, Glace Bay, Children's, Grace Maternity, and Victoria General Hospitals, and Halifax Infirmary, Halifax, Aberdeen Hospital, New Glasgow, City Hospital, Sydney, Yarmouth Hospital, Yarmouth. The New Waterford General Hospital has been "conditioned"

The new Hospital for Infectious Diseases, Halifax, was opened for the reception of patients on October 25th. Only a single patient had to be transferred from the old hospital. The new building, which is situated in the hospital area in immediate proximity to the Dalhousie Medical School, is well planned and admirably equipped. The normal accommodation is for forty-two patients, but this can be readily expanded to provide for fifty. There is abundance of open space about the building, and the orientation allows of all wards being flooded with sunlight. It may be remembered that there was considerable opposition to the erection of this hospital, and that a mayor of the city resigned because of the support given to the undertaking by the City Council. The credit for the origination of the enterprise, and for pushing it through to completion, is due principally to Dr W D Forrest, Chairman of the City Health Board, who was indeed fatigable in overcoming difficulties and opposition of one kind or another.

The officers of the Medical Society of Nova Scotia, elected at the seventy-fifth annual meeting, are as follows: President, Dr R H Sutherland, Pictou; Vice-presidents, Drs G W T Farish, Yarmouth, and A. Calder, Glace Bay; Secretary, Dr Smith L Walker, Halifax; Treasurer, Dr J G D Campbell, Halifax. Next year's meeting is to be held at Pictou.

An extended reference to the annual meeting of the Medical Society of Nova Scotia, with the several functions associated or combined therewith, will be found elsewhere in this issue of the *Journal*. The program attracted the largest attendance ever recorded at a meeting of the provincial society. Dr Smith L Walker, the energetic secretary of the Society, has received many well deserved words of praise for initiating and forwarding the scheme which was executed so satisfactorily.

Tetanus, which is by no means a common condition in Nova Scotia, has recently been responsible for two deaths in the province, both occurring in the vicinity of Bear River. In neither case was medical aid summoned early enough to permit of the successful use of anti-tetanic serum.

Dr M A B Smith, of Dartmouth, has gone to London for some months of study in the hospitals there. He will visit several European medical centres before he returns home.

Dr Byers, of East Orange, New Jersey, who was

associated with Dr Pitkin in the production of spino-caine, was a recent visitor at Amherst, where he assisted at the first operation with spinocaine as the anæsthetic attempted in that town.

Dr Evelyn Rogers (Dalhousie, 1927), after serving for a year as interne at the Englewood, New Jersey, Hospital, has accepted an appointment on the medical staff of the Nova Scotia Sanatorium, Kentville.

Early in November, a class of nine nurses graduated from the training school of the Nova Scotia Hospital. The large recreation hall of the hospital was brilliantly decorated for the occasion. The graduates were addressed in appropriate terms by Dr K. A. MacKenzie. The ceremony was followed by a very enjoyable dance in which the nurses and their guests participated.

At the annual meeting of the Nova Scotia Medical Society Dr A C Jost, Provincial Health Officer, was elected Chairman of a Committee on Historical Medicine. Two interesting letters from the late Sir Charles Tupper, M.D., were presented during the meeting to the archives of the Society. W H HATTIE

The Medical School of Dalhousie University announced the appointment as Assistant to the Chair of Pathology and Bacteriology of Dr Clyde W. Holland, a Dalhousie graduate of 1923. Except when doing post graduate work in London, Dublin and New York Dr Holland has, since graduation, been associated with the staff of the university. He graduated in Arts from the university in 1916.

The 22nd Field Ambulance Dinner was held at the City Club October 8, 1928. Col H A. Chisholm, Officer Commanding, presided with Major J G D Campbell, as Vice, proposing the Toast to the King. Officers of the Ambulance present were Captain S H Keshen, Prov Lieut H N Gosse, and Prov Lieut W J Keating. Among the guests were Major Gorshline, S.M.O., M.D. 6, Major Murray and Captains of the R.C.A.M.C., Lieut Victor Mader of the Artillery and Major C S Major, Quarter Master. A pleasant feature of the evening was the presentation, by Captain Keshen on behalf of the Ambulance, to Major Murray of a sterling silver fruit bowl, as an appreciation of his services during the Aldershot Camp of 1928. Colonel Chisholm commented on the very pleasant relations existing between the Militia and Permanent Medical services. The Ambulance now has a special Officers' Mess in the Armouries and Badminton winter contests will soon be under way. First Aid and other training will also be carried out for the men.

District Military Orders, M.D. 6, issued October 23, 1928, contain the following item—

No 9 (Reserve) Stationary Hospital, C.A.M.C. Major S L Walker to command the Hospital, with effect from the first of April, 1928 (M.O. 459/1928)

NEW BRUNSWICK

The first extra mural team to visit New Brunswick this autumn received a flattering welcome throughout the province which was richly deserved.

Dr R R Fitzgerald, of the Goitre Clinic of the Montreal General Hospital, classified the types of goitre commonly met with, emphasized obscure symptoms, and stressed the necessity for careful iodine therapy. He also stated that operation at the proper time was the one successful method of treatment.

Dr D S Lewis, of the Royal Victoria Hospital,

Montreal, needed no introduction to his audiences. He discussed oedema and illustrated his program by a well-planned lantern demonstration.

Both gentlemen handled their subjects with a facility that argued for their exact knowledge of the subject under discussion.

At a recent meeting of the Provincial Red Cross Society most encouraging reports were received from the outpost hospital at St Leonard's which has pro-

vided most necessary services which would otherwise have not been available. A special request was received for an organization of another outpost hospital at Claro in place of the present private hospital of Dr LaPorte. There has been already a request for an outpost hospital on the Island of Grand Manan. These areas although not far removed from large centres are yet unbenefited by methods of rapid transportation. It is to be hoped that the Red Cross funds will be sufficient to provide these desired services.

At the meeting of the Provincial Government, held in Moncton on October 20th, Dr J. A. Melanson was appointed to succeed Dr G. G. Whorrett as Travelling Tuberculosis Diagnostician. His headquarters will be at Rivier Glade. Dr Melanson is a graduate of Edinburgh University and is a son of Hon. O. M. Melanson.

The delegation of Public Health Officers from New Brunswick to the meeting of the Canadian Public Health Association at Winnipeg included Dr G. G. Melvin, Chief Health Officer, Dr Wm. Warwick of Saint John, and Dr C. W. McMillan, Provincial Tuberculosis Diagnostician. These gentlemen intend to take in the meeting at Chicago on their return journey.

Miss Mary F. Bliss, Superintendent of the Soldiers' Memorial Hospital at Campbellton, has resigned her position to accept a similar position in Guelph.

Dr A. B. Walter, late of Cambridge, is at present doing some hospital work in Montreal previous to his removal to Saint John where he will practise in the future.

Dr Geo. Skinner, of Saint John, has returned to his practice after a month's study in New York.

Dis. L. M. Currien, G. A. B. Addy, A. E. Macaulay

and D. C. Malcolm attended a meeting of the American College of Surgeons in Boston.

Dr E. W. Lamer, of Saint John, attended a meeting of the Canadian Anesthetists' Society which was held in Boston in conjunction with the meeting of the New England Society.

Dr J. M. Cruikshanks, of Saint John, sailed on September 24th to assume the duties of his new appointment as Medical Officer in charge of medicine and surgery in the British Government Hospital at Nassau, Bahamas.

Dr J. Boyle Travers, of the staff of the Provincial Hospital, has been holidaying in Prince Edward Island.

At the meeting of the Canadian Public Health Association at Winnipeg, Dr William Warwick, of Saint John, was elected Vice President of the Association.

Dr Maves Case, of Saint John, has returned from a trip to Upper Canada and the Eastern States.

Dr G. Clowes Van Wart attended the meeting of the American College of Surgeons at Boston.

Dr Geo. M. Beller has begun practice in Woodstock, where he will specialize in surgical branches.

The Boston papers announced the wedding of Dr Levi M. Currien to Elizabeth McLean on October 10th.

Dr and Mrs J. V. Anglin were recently in Halifax. Dr Anglin represented Queen's University at the Diamond Jubilee Celebration of Dalhousie University.

Dr W. O. Chestnut of Hartland has been recently visiting his family and friends in the southern part of the Province.

A. STANLEY KIRKLAND

QUEBEC

The fact that not one baby died at the Montreal Foundling and Baby Hospital, St. Urbain Street, during last summer—a time fatal to so many children—was cited as a proof of the health-giving conditions the little inmates enjoy at the hospital, where a reception was held recently, to show the new isolation cubicles, which have just been completed. The new ward of six cubicles has been made possible largely from the funds of "Violot Day" with special donations, notably that of Dr A. D. Blackader, who furnished the glass partitions which make each cubicle sufficient unto itself. All babies, on first arrival, are put for two weeks into this isolation cubicle ward, so as to guard against infection being brought in. The cubicle gallery has the most modern hospital equipment, and its walls are mostly of the "vita ray" glass through which the curative rays of the sun can penetrate. There is a sun parlor in the main building, where groups of children spend day and night with decided advantage to their health. There are usually some 70 children under two years of age in the institution, and their healthful condition is ascribed to the modern equipment of the hospital, and the personal care given under the expert supervision of Miss L. C. Phillips, the Superintendent, and her assistant, Miss L. Lawrence.

The new Bourget Sanatorium, a wing of the St. Jean de Dieu Hospital, Longue Pointe, was formally opened by His Grace Archbishop Gauthier. The new wing, which is a fireproof building in the form of the

letter "H", is fitted with the most modern equipment and includes, in addition to wards for observation and treatment, nurses' class rooms, laboratories and doctors' offices. In his address, the Archbishop pointed to the remarkable progress made by St. Jean de Dieu institution, and paid tribute to the University of Montreal for its large share in this work. Dr. Gaston de Bellefeuille, in reply, traced the hospital's history since its founding as the Longue Pointe Asylum in 1873, touching on the changes in treatment of the mentally diseased since that time. Other speakers included Dr. F. E. Devlin, Dr. A. G. Desloges, and Dr. L. E. Pariseau.

Colonel John McCrae, author of "In Flanders Fields", was honoured quietly in a private ceremony at McGill University, when a small oak tree, presented to McGill by the Teachers' College of the University of Georgia, was planted to his memory on Armistice Day. In the presence of a few intimate friends of the late Col. McCrae, the oak acorn was rooted in McGill soil near the medical building where the poet served as a member of the staff of the faculty of medicine prior to going overseas. Brig. Gen. Birkett presided at the planting, and an ode commemorating the poet and his poem was read by the author, C. Benedict. It was stated at McGill that, as the tree arrived from the University of Georgia so shortly before the actual planting, the ceremony was held privately because there was not time enough to notify many friends.

By a decision that all medical school inspectors in Montreal shall be employed full time by the city, whereas in the past some of them have given but a part of their time to these duties the effect will be that the city will have an additional service equal to the engagement of three new inspectors. The Executive Committee received the resignation of Dr J I Laberge, head of the contagious disease section of the Health Department. Dr Gervais, assistant to Dr Laberge, has been appointed to fill the vacancy, and Dr Laberge retires on pension.

Fifty new employees have been added to the Montreal health department since re-organization started in this service last spring. This, along with equipment redistribution of expenses, etc., means an added allocation for the health department of \$150,000 a year.

The milk and meat inspection staffs are now completely reorganized, each under a supervisor. Three

veterinaries have been added to the staff, who will divide their work between milk and meat.

Several inspectors have been added to the plumbing section, for examination of sanitary equipment in houses, etc., while the corps of school medical inspectors and school nurses have been filled since early fall.

Two supervisors of inspectors have been appointed to direct the work of the various food, meat and restaurant inspectors.

There remains to be appointed an assistant director of public health to assist Dr S Boucher, Medical Health Officer. This official will be named within a short time, it was stated, as the city authorities have a prospective nominee in mind.

All in all, the health department is now on an efficient working basis, and satisfies the conditions made by the Provincial and Federal Governments and by the American health authorities in regard to milk inspection.

GEORGE HALL

ONTARIO

The annual post graduate course given under the auspices of the Alumni Association of the University of Western Ontario Medical School was attended by about one hundred doctors and was given at Victoria Hospital, London, in conjunction with the district meeting of the Ontario Medical Association. Clinics and lectures were given by Drs J A Macgregor, Hadley Williams, F J H Campbell, F W Luney, J H Geddes, R A Johnston, J T Bowman, G C Hale, J A Oille, Toronto, Dr R V B Shuer, Toronto, O M Wilson, Ottawa and C P Hutchins, Syracuse, N Y.

Prof Andrew Hunter, head of the Department of Biochemistry in the University of Toronto, has resigned and will go to Glasgow University in the spring, where he will hold the chair of physiological chemistry.

The Ontario Hospital Association held its fifth annual convention in Toronto, on October 18th and 19th, meeting at the Academy of Medicine. A very comprehensive program was provided, one which dealt with most of the problems that are met with in hospital administration. Addresses were made by Canon Cody, by

the Honourable Lincoln Goldie, by Dr McEachren, Director of Hospital Activities of the American College of Surgeons, and by Dr Harvey Agnew, Secretary of the Department of Hospital Service of the Canadian Medical Association.

One notes with interest the discussion on the subject "Should nurses take oral orders from physicians?" and the debates on other problems equally important. On Friday afternoon the association visited the new convalescent hospital at Thistlethorn, built by the Hospital for Sick Children for its convalescent cases. The annual dinner of the association was held at the King Edward on Thursday evening.

The new hospital at Thistlethorn, a hospital for the reception of convalescing children from the Sick Children's Hospital in Toronto, was opened on October 24th. A description of this hospital and the interesting ceremonies in connection with its opening will be given at a later date.

The fifth annual St Luke's Day service of the Academy of Medicine in Toronto took place in the

MAKE PLANS NOW FOR NEXT MAY

Come to HAMILTON for the

Forty-ninth Annual Convention

of the

Ontario Medical Association

MAY 28 - 29 - 30 - 31 - 1929

Outstanding Speakers - Abundance of Clinical Material

Golf Courses second to none - Class Reunions

chapel of Victoria College on October 21st, at 11 a.m. The service was well attended and the many members of the Academy who were present appreciated the kindness of the authorities of Victoria in permitting them to take part in the religious exercises provided, and to listen to the stimulating address delivered by Chancellor Bowles. The Academy has felt that the St. Luke's Day service should be continued, and announces that through the kindly consent of the authorities of the various college chapels about the uni-

versity campus a service will be held each year in one or other of these chapels. It is planned to make St. Luke's day service a ceremony in which all Fellows of the Academy will be interested, and it is hoped that year by year one will see a larger and larger procession leaving the Academy building, suitably, or even gorgeously, gowned in academic robes, to take part in the religious exercises which celebrate the day set apart for Medicine's patron saint. N. B. Gwyn

MANITOBA

The cornerstone of the new Deer Lodge Military Hospital was laid, on October 27th, by J. T. Thorson, M.P., member for South Winnipeg. Dr. J. A. Amvot, Deputy Minister of Pensions and National Health, and Dr. Ross Millar, of Ottawa, were present at the ceremony. Dr. Amvot stated that the new building would serve to extend the present facilities greatly and alleviate a serious hospital shortage in Winnipeg for ex-service men.

The Department of Health and Public Welfare of Manitoba issued its first news bulletin on November 1st. During the month of October the following communicable diseases were reported: diphtheria 32, anterior poliomyelitis 20, scarlet fever 39, measles 19, smallpox 1, typhoid 11, tuberculosis 4, ophthalmia neonatorum 1.

Dr. J. W. Crane, University of Western Ontario, London, was a welcome visitor in Winnipeg from November 16th to November 19th. On November 16th he addressed the Winnipeg members of the executive of the Manitoba Medical Association at lunch, and in the evening the Winnipeg Medical Society at its regular meeting. On November 17th, he addressed the medical students. Dr. Crane is chairman of the section of Historical Medicine in the Canadian Medical Association.

Hon. Dr. E. W. Montgomery, Minister of Health and Public Welfare, returned recently from attending the annual meeting of the American Public Health Association at Chicago. On his trip he proceeded to Ohio and Tennessee and made investigation of the rural health area scheme in operation in these states for a number of years. Dr. C. B. Covington, of the Rockefeller Foundation Institute, was in Manitoba recently in connection with proposals to establish district health areas in this province.

The annual meeting of the Board of Governors of the Winnipeg General Hospital was held on Novem-

ber 3rd. Dr. G. F. Stephens, the Superintendent, pointed out that, with the daily average of patients for the entire year reaching 609, the ratio of occupied beds was 94.4 per cent. A ratio of 85 per cent average occupancy is considered the limit of safety for a general hospital which takes in accidents and emergency work. The question of enlarging the hospital is being considered.

The annual armistice day service at the Medical College under the auspices of the Medical Alumni Association was held on November 10th. Dr. B. J. Brandon presided and Dr. William Boyd delivered an eloquent address.

At the meeting of the Winnipeg Medical Society on October 19th, Dr. D. S. Moorhead read a paper on "Pyloric spasm," and Dr. A. J. Fraser, Medical Officer of the Workmen's Compensation Board, a paper on "Infections of the hand." At the meeting on November 16th the following program was presented: "Organization of a full time rural health unit," Hon. Dr. E. W. Montgomery, "The heart, the great vessels and the brain," Dr. Digby Wheeler, "Diet and disease," Dr. J. W. Crane, London, Ont.

Dr. C. A. Branger, Superintendent of the Brandon Mental Hospital, has been promoted to the rank of lieutenant colonel, and to command No. 21 Cavalry Field Ambulance R.C.A.M.C., located at Brandon, vice Lieut. Col. and Brevet Colonel C.P. Templeton, C.B.E., D.S.O., V.D.

Dr. C. R. Gilmour has been appointed physician to, and chief of the department of medicine in, the Winnipeg General Hospital.

Dr. Lennox Arthur has been appointed Assistant in Obstetrics (Out Patient Department) at the Winnipeg General Hospital. ROSS MITCHELL

SASKATCHEWAN

At a recent reorganization meeting of the Eastern Saskatchewan Medical Society the following officers were elected: Honorary President, Dr. Elliott, Wolsley, President, Dr. Munroe, Welwyn, Vice President, Dr. Chestnut, Moosomin, Secretary-Treasurer, Dr. J. A. Keyes, Fleming.

At a recent scientific meeting of the Eastern Saskatchewan Medical Society Dr. George Craig, of Broadview, gave a paper entitled "The therapeutic value of rest in the treatment of disease," and Hon. Dr. E. W. Montgomery, of Winnipeg, spoke on "Research work on pernicious anemia as carried on by the medical staff of Manitoba University." The Moosomin Canadian Club entertained the Society members at dinner, when Dr. Montgomery again spoke, the topic of his address being "Six hundred miles of travel in northern Manitoba by canoe."

On October 20th the Eastern Saskatchewan Medical Society was visited by a post graduate team composed of Dr. H. H. Hepburn, of Edmonton, and Dr. W. A. Merritt, of Calgary. As this date fell on Saturday the attendance was rather poor, but those present discussed the papers enthusiastically. Dr. A. McG. Young, who accompanied the team, also addressed the meeting. J. A. KEYES

Dr. Ross Miller, Chief Advisor of the Department of Pensions and National Health, Ottawa, visited Regina on October 22nd. He held a conference with the medical men of Regina who are engaged in the work of the Soldiers' Civil Reestablishment. Dr. Gordon Young, of Moose Jaw, and Dr. Cox and Dr. Creighton, of Saskatoon, also attended the conference. Dr. Miller addressed the war veterans in both Moose Jaw and Regina.

A Vitamin-containing food —and very much more

Whilst the presence of vitamins in food is rightly recognized as essential, their presence is a minimum and not a maximum requirement. Whilst Virol contains all the vitamins, it does not, like so many foods, found its claim to medical attention on its vitamin content alone.

In Virol the relative proportions of Protein, Fat, Carbohydrate and Mineral Salts are carefully adjusted. For it is recognized that the absence or deficiency of one element leads to the inefficient absorption of the other food elements present in the diet. Thus

Virol is a food complete in itself and correctly balanced

A Food, again, must be judged by the amount and nature of the products of its digestion that ultimately reach the blood. In Virol the fat is presented in the form of a highly digestible emulsion, and the proportion of protein is adjusted so as to avoid derangement of nitrogenous metabolism.

The proof that Virol conforms to all the essential canons of the science of nutrition is seen by the fact that

VIROL

is used in over 3,000 Hospitals
and Welfare Centres

VIROL LTD, HANGER LANE, EALING, LONDON, W 5
Sole Importers Bovril Limited, 6201 Park Avenue, Montreal
Sales Agent Harold F Ritchie & Co Ltd, 10 McCaul St, Toronto

The staff of the Grey Nuns' Hospital, Regina, held their monthly meeting after a lunch on October 25th. Dr T. A. Morrison and Dr A. S. Gorrell each reported a case of Hodgkin's disease. Dr U. Gareau reported a case of pyloric stenosis in a child.

The Saskatchewan Anti-Tuberculosis League has circularized the physicians of the province asking them to co-operate in the examination of the "under par children" reported to the League. A fee of five dollars will be paid by the League for the first examination of each patient, and two dollars for each subsequent examination. Saskatchewan had a tuberculosis death rate of 46 per 100,000 population in 1927, which is the lowest rate in any of the provinces.

Dr H. H. Hepburn, F.R.C.S., Assistant Professor of Surgery, University of Alberta, and Dr W. A. Merritt, of Calgary, have just completed an extra mural postgraduate tour. Meetings were held at North Battleford, Prince Albert, Wadena, Saskatoon, Broadview, Regina, Moose Jaw, Weyburn, and Swift Current. Owing to unfortunate circumstances at two points the meetings were not as large as desirable. At all other points however, the meetings were very well attended, and were highly appreciated by those present. Dr Merritt spoke on the subjects of "Peptic ulcer," "Nephritis, acute and chronic," and "Encephalitis." Those given by Dr Hepburn were "The treatment of head injuries," "The surgical treatment of neuritis and neuralgia," "Common lesions of the brain and spinal cord." Dr A. MacG. Young, General Secretary-Treasurer, accompanied the visiting team on this tour and discussed matters of interest to the profession.

The births in Regina the first nine months of this year numbered 1,115, the deaths of infants under one year of age numbered 63. This death rate is below that of former years.

Physicians in the city of Regina and throughout the province are elated at the judgment given last week in a test case in Arcola District Court.

Municipalities throughout the province have long taken the stand that while they should pay hospital bills for patients, who are unable to do so, from their communities, it was not their duty to meet the bills of attending physicians. The judgment holds municipalities are also responsible for physicians' bills.

Dr W. R. Coles sued the rural municipality of Wawken for a fee of \$125 for attending Bobby Brickley, aged two years, for a period of 111 days in the Grey Nuns' Hospital. The boy's right arm had been badly injured and burned making it necessary for Dr Coles to do some skin grafting.

The municipality paid \$277.50 to the hospital, but refused to meet the doctor's bill, taking the stand that on the grounds of the Rural Municipality Act they were not compelled to make such payment to a physician.

Judge Rimmer gave judgment against the municipality.

Dr Gordon Wells and his wife, Dr Alice Mooney Wells, who are both graduates of the University of Toronto, have recently come from Flaxton, North

Dakota, to Weyburn. They were accompanied by their two sons and two daughters.

Dr R. E. Brown, who has been at the Regina General Hospital, has now begun to practise at Balcarres.

Dr A. S. Simpson, of Maple Creek, has associated himself in practice with Dr R. V. McCarley, of North Vancouver, and is now located in that city.

Dr F. F. Dunham, who has been practising at Girvin, has moved to Rocanville.

Dr J. L. A. Aubin, who for several years has been at Willowbunch, is now practising at Hearst, Ontario.

Dr D. M. Baltzan, who has been on extended post graduate work in Europe and the United States, has returned to Saskatoon.

Dr B. Stoller, has begun practising at Regina.

Dr A. Belkin, a recent graduate of Manitoba, has opened an office in Tomkins.

Dr M. D. Mitchell formerly of Piapot, has moved to Maple Creek.

Dr L. Beaudoin, who practised formerly in Regina, has moved to Ponteix.

Dr R. S. Conn, of Regina, has moved to Francis.

Dr E. W. Seale, of Whitewood, sold his practice to Dr S. W. Baker. Dr Seale has moved to Brandon, Manitoba.

Dr F. B. Walsh, Estevan, has just returned from Edinburgh, where he was successful in obtaining his F.R.C.S.

Dr L. M. Fairbairn is now practising with Drs Creighton and Walsh, of Estevan.

Dr James Brown, of Bromhead, where he practised for many years, has moved to Oungre.

Dr I. E. Brouse, formerly of Vibank, has moved his office to Tuxford.

Dr T. D. Kendrick has begun practising at Earl Grey.

Dr L. Jordani, who was House Surgeon at the Regina General Hospital, has opened an office at Willowbunch.

Dr Boris P. Batanoff is now at Blaine Lake.

Dr A. W. Brodie, who formerly practised at Blaine Lake, has returned from taking post graduate work in Great Britain and the Continent, and is practising in Prince Albert.

Dr S. U. Baker, formerly of Buchanan, has taken over the practice of Dr C. Seale, of Whitewood.

LILLIAN A. CHASE

BRITISH COLUMBIA

Dr G. L. Milne Honoured

"It is but a fitting tribute to Dr G. L. Milne of this city that he should have been made a life member of the Victoria Medical Society. It is a supplement to the honours he has already received in this direction, for he is an honorary life member of the British

Columbia Medical Association, and also enjoys a similar privilege in the larger Canadian Medical Association. Dr Milne's work as a practitioner is widely known. He has earned the title of "Father of the Medical Association" in this province, and during his years of active practice he did very much to build up that body.

UNKNOWN FACTORS

in

COD LIVER OIL

SINCE the determination of the presence of certain vitamins in Cod Liver Oil and the essential place of these vitamins in the human diet, there has been a frantic effort to isolate them and to develop laboratory products which could replace Cod Liver Oil for many of its present uses

Used For Centuries

Because of its therapeutic value Cod Liver Oil has been used for centuries, but the true cause of its value has never been fully determined. For some time we have known it to be the richest source of Vitamin A and for a shorter time we have known it to be the richest source of Vitamin D. What other values it possesses we do not know.

Further Research Needed

In the excitement and enthusiasm naturally produced by these truly progressive steps in vitamin research we should not lose sight of the fact that further research into the therapeutic value of Cod Liver Oil must be conducted before these new substances can be legitimately thought of as true substitutes for Cod Liver Oil.

AYERST COD LIVER OIL

Obtained from selected sources in Newfoundland

Biologically tested in our own laboratories

Guaranteed to contain 500 Vitamin A units and 75 Vitamin D per Gm or better

Carbonated by a special process which preserves the vitamin content and renders it

MONTREAL - 71 William Street - CANADA

to the high place it now occupies in the medical life of the province. His labours in the cause of medical science well deserve the triple recognition with which he has been honoured. To him and his colleagues of the time, in 1886, is due the passage of the original Medical Act of the British Columbia Legislature, which insured that only qualified men would be permitted to practise in the province.

Dr Milne, some years ago, retired as Inspector of Immigration and Controller of Chinese Immigration at this port, a post which he occupied with entire satisfaction to the Dominion Government and the public at large. In this task and in the many other activities in which he engaged in connection with the Medical Health service of the Dominion Government he rendered always faithful and efficient duty and enjoyed the respect of all. He has been in British Columbia for nearly half a century and the local medical society is to be congratulated on having seized upon this fact to do him an honour which he so well deserves. The hope will be expressed by his numerous friends that he will be long spared to enjoy a rest which is the reward of the conscientious endeavour he has always shown" (*The Victoria Colonist*).

Dr J W Woodley, of the Pensions' Board, has recently been transferred to Calgary.

The new hospital at Nanaimo is now in operation
C H BASTIN

The new Medical & Dental Building is at last on the way to becoming more than a dream. The contractors are now busy on a fifteen storey building on Georgia Street, directly across the street from the new Canadian National Railway Hotel, work on which is to begin this month. Already the British Columbia and Vancouver Medical Associations are making arrangements for joint executive offices in the new building, and the Library of the Vancouver Medical Association will be on the same floor. The building is to have an auditorium in which it is hoped all medical meetings will be held. It should be ready for occupation towards the end of the summer of 1929.

A committee of the Vancouver Medical Association has been engaged during the past few weeks on a survey of the public health situation in the city having in view the changes and rearrangements that will be necessary when the amalgamation of the Municipalities of Point Grey and South Vancouver with the City of Vancouver takes effect at the beginning of the year.

J M PEARSON

UNITED STATES

Cancer Control and the American Public Health Association

An event of much importance to cancer control in the United States took place at Chicago in the week beginning October 15th, when the American Public Health Association, with an attendance of 2,400 members, mostly professional health workers, held its fifty seventh annual meeting.

The principal feature of the convention was a cancer symposium under the chairmanship of Dr Charles H Mayo, with addresses on early diagnosis, the epidemiological approach to cancer, heredity, a cancer clinic and what it is necessary to do about cancer. Dr Mayo himself expressed a belief in the inheritability of a susceptibility to cancer, and made a plea for a central organization which should serve as a clearing house for information on cancer.

The Association adopted the report of its Cancer Committee recommending that responsibility for leading and otherwise promoting cancer control activities in a state or community be definitely placed in the hands of a committee composed of, (a) the head of the public health department, (b) a representative elected by the organized medical profession, and (c) a representative of the American Society for the Control of Cancer.

The Committee on Administrative Practice of the American Public Health Association presented a revision of the Appraisal Form for city health work in which cancer is named as an activity to be taken fully into account in rating the value of public health work, listing it with sanitation, the control of communicable disease, etc.

Announcement was made of the appointment of a National Cancer Committee with members in all parts of the United States and a local Cancer Committee in Chicago to investigate new methods in fighting cancer and to serve as a centre of information in all phases of the cancer question.

A new committee on cancer statistics appointed by the Section on Vital Statistics to devise standard methods of collecting and expressing statistics of cancer in which the errors which have so often invalidated such records shall be as far as possible eliminated. It is possible that the work of this committee will entirely change existing statistical methods in relation to this disease.

A decision was made to devote an entire session of the Section on Statistics to cancer at the next annual meeting.

Septic Sore Throat in Lee, Mass

In a recent issue of the *Weekly Bulletin* of the Department of Health of the City of New York it is stated that an epidemic of septic sore throat broke out in Lee, Massachusetts, in July. Within two weeks there were nearly 600 cases, with thirty six deaths, in a population of about 4,000. The epidemic ended abruptly on the enforcement of a local order requiring pasteurization of milk, thus followed the recovery of hæmolytic streptococci from a cow and from a number of persons concerned with a dairy. Contact cases were very few.

Nine Medical Colleges Pass the Century Mark

The following tabulation will be of interest in noting the time of service of centenarian medical schools in the United States. This year the University of Pennsylvania School of Medicine begins the one hundred and sixty third session, Harvard University Medical School begins the one hundred and forty sixth session, University of Maryland School of Medicine and College of Physicians and Surgeons begins the one hundred and twenty second session, Columbia University College of Physicians and Surgeons begins the one hundred and twenty first session, Yale University School of Medicine begins the one hundred and fourth session, Jefferson Medical College begins the one hundred and fourth session. The University of Virginia Department of Medicine, the Medical College of the State of South Carolina, and the University of Georgia Medical Department begin their one hundredth session.—*Virginia Medical Monthly*

Gift to the University of Chicago

At the ceremonies connected with the dedication of the chapel of the University of Chicago, Mr John D Rockefeller, Jr, is reported to have said "As president of the Laura Spelman Rockefeller Memorial I am authorized to offer to the university an endowment fund (of \$1,000,000) to be known as the Laura Spelman Rockefeller Memorial fund, to be used to promote the religious idealism of the students of the university, through the broadest and most liberal

Biggs Professorship in Preventive Medicine

The Herman M. Biggs Memorial Fund gave more than \$55,000 recently to New York University and Bellevue Medical College to establish a professorship in preventive medicine in Dr. Biggs' name.

Alvarenga Prize of the College of Physicians and Surgeons

The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about three hundred dollars, will be made on July 14, 1929, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered.

An essay intended for competition may be upon any subject in medicine, but must be accompanied by a written assurance from the author that it has not appeared previously in print, either in whole or in part, in any form, and has not been presented elsewhere in competition for a prize. The essay should represent an

addition to the knowledge and understanding of the subject based either upon original or literary research. It must be typewritten, and in English acceptable for publication without necessity for editing by the Committee. Any illustrations should be appropriate and correctly annotated with the text. Essays must be received by the Secretary of the College on or before May 1, 1929.

Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author.

It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College, and that it may be published by the author with the consent of the College; other essays will be returned upon application within three months after the award.

The Alvarenga Prize for 1928 has been awarded to Drs. J. A. Paul and W. W. McClellan, Philadelphia, for their essay entitled "A pathological study of the pleural and pulmonary lesions in rheumatic fever."

JOHN H. GRIVIN, *Secretary*,
19 South 22d Street, Philadelphia, Pa.

GENERAL

The League of Nations on Syphilis

The Health Organization of the League of Nations has published the deliberations of a group of experts* on syphilis and cognate subjects held under its aegis at Geneva in October last. The matters discussed were chiefly (1) the prevention of syphilis, and (2) the teaching of modern methods of treatment, together with the standardization of drugs used.

It was pointed out that in the fight against syphilis the results have not been what the progress of syphilis therapy would give reason to suspect. This seems to be because the new discoveries are not exploited to their fullest extent, and no uniform generally recognized method of treatment exists.

It is suggested by the Committee, therefore, that a statistical compilation should be made regarding the various methods of treatment in clinics, dispensaries, etc., to permit of a better general idea of their efficacy. This compilation would be made by the various clinics sending to the Health Section of the League individual case records which could be worked up and the conclusions tabulated. This would require the reporting of a large number of cases, and also the working up of these cases over a given period of time. The Directors of Clinics would be asked also to prepare a general statement of the principles they applied in their treatment.

The importance of theoretical and practical training for students in syphilology was emphasized. In the view of the Committee, the state should facilitate in every way continuation courses in syphilology for general practitioners and medical officers.

As regards the drugs used in treatment of syphilis, the Committee was of the opinion that it is highly regrettable that bismuth preparations should be placed on the market which do not correspond to the manufacturers' indications. Certain countries have adopted the plan of officially testing these preparations, and this method should be made widely known, perhaps through the Health Organization of the League itself.

* These were of Professor Jadassohn of Breslau (chairman), Dr. Th. Madsen of Copenhagen, Colonel L. W. Harrison of London, Dr. Louis Quoyrat of Paris, Dr. J. H. Stokes of Philadelphia, and Prof. C. Rasch of Copenhagen.

The Pan American Medical Association

The next congress of the Pan American Medical Association will be held in Havana, Cuba, from December 29, 1928, to January 3, 1929. The program which is being arranged by the President, Dr. Fred H. Albee, of New York City, will be a strong one, and will include four orations, upon the subjects of surgery, medicine, pediatrics, and tropical medicine.

Dr. William J. Mayo will give the Oration on Surgery, and Dr. Lewellys Barker, of Johns Hopkins University, the Oration on Medicine. Papers will be read in both Spanish and English.

This congress will be representative of the medical profession of the entire western hemisphere. Chapters of the Association have been and are being organized in various centres of North and Central America, as well as in the Antilles, all of which will be represented at the congress.

One of the recent accomplishments of the Pan American Medical Association is the establishment of the Pan American Hospital in New York City for the benefit of the Latin speaking peoples.

The Secretary is Dr. Conrad Berens, 30 E. 40th St., New York City.

Rockefeller Fellowships in Dublin University

Within the last few months the trustees of the Rockefeller Foundation have given their assent to a scheme for the establishment of research and teaching fellowships in connection with the medical school of Dublin University, and three fellowships, each worth £500 a year, have been provided. One came into being on October 1st, another will be created in October, 1929, and a third, two years later. The fellowships are residential, and each holder will be required to work in a department of Trinity College Medical School, mainly on research, but with some teaching as part of his duties. The present scheme is tentative in character, and will be subject to review after five years. Under the scheme Dr. R. A. Q. O'Meara, M.Sc., has been nominated as Rockefeller Foundation Fellow in Public Health, his appointment dating from October 1st.

The Nobel Prize

The Nobel Prize for Medicine for 1928 has been awarded to Professor Charles Nicolle, Director of the Pasteur Institute in Tunis, for his work in connection

*Steam
Rendering
Vats*

Steam Rendering of Cod Livers

Much of the unpleasantness in the taste of cod liver oil was eliminated when steam was introduced to remove the oil from fresh livers. The old method, when the industry was in its infancy, was to allow the livers to rot in open barrels in the sun. Putrefaction and nature were relied upon under the old order. Science and progress mark the new.

This added to the fact that only about an hour's time elapses from the time the fish are

Vs Rotting

caught until the livers are in the rendering vats, accounts in large measure for the superiority of Mead's Standardized Cod Liver Oil.

But before rendering, each liver is examined and thoroughly washed. Bile infected and small livers are thrown out. These are all preparatory precautions.

And now Mead's Cod Liver Oil can be had with the addition of agreeable essential oils—permanently flavored—with no diminishing of potency or injury to the patient.

and the red corpuscles. The principal components of the two phases are stated to be water, carbon dioxide, oxygen, hydrochloric acid, together with all other acids except proteins which are combined with base. The sum of all the bases (except protein) of the plasma, the sum of all the bases (except protein) of the cells, the sum of the proteins of plasma, the protein of the cells, these are the variables with which the book deals.

Three physiological functions of blood are considered: that of environment of the organs and tissues, those of vehicle for the transport of oxygen and carbonic acid between lungs and tissues and for transport of water and glucose, and that of regulation of temperature. The properties of the components of the blood are shown to be highly adapted to the function of preserving the constancy of the environment of cells and tissues and to the function of transporting carbonic acid and oxygen.

The book sets out the results of the author's own work and its scope is indicated by an enumeration of the headings under which the material is presented. These are, following the introductory chapters, acid base equilibrium, dissociation curves, cells and plasma, the physico-chemical system, the respiratory cycle, blood and circulation. Then follow chapters in which are considered variations in the composition of the blood during work, in disease, and of other species. A chapter entitled "Circulatory Adaptations" has to do with studies of the physiological changes in four men while riding a stationary bicycle.

In summing up, we find, to use to some extent the author's own words, that the respiratory activity of the blood has been related to certain aspects of general physiology, a quantitative study of the physico-chemical system blood has been made, the respiratory cycle of the blood has been analyzed, the relations between the properties of the blood and its cycle and between the properties of the blood and those of the circulation and respiration, have been stated. Further, there is a comparative quantitative description of the blood in rest and work, in health and disease, and from species to species, with a corresponding description of the respiratory cycle of blood, and, finally, a description of the mutual dependence of the properties of blood and of the circulation, respiration and metabolism. The style in which it is written and the order of presentation make the book readable and understandable. The treatment is mathematical throughout and the text is supplemented and illustrated by a profusion of charts and diagrams. The use of equations, contour line charts, and nomograms makes it possible to present many facts and relations in a clear and concise manner. To the physiologist who is mathematically inclined the book should be a delight. The mathematical treatment of a biological subject has its defects as well as its advantages, but in this case one is conscious only of the advantages.

A. W. DOWNS

Modern Problems in Neurology Kinnier Wilson, M.D. B.Sc. (Edn.), F.R.C.P. 364 pages, illustrated. Price 21/- net. Edward Arnold and Co., London, 1928.

The author has collected in this volume a series of his own papers which have appeared in journals in recent years, all dealing with subjects that have been prominent lately. The papers have been revised for this volume and new material has been incorporated in most instances.

In the first four chapters, Wilson considers the epilepsies, their variants and related phenomena, and gives simple and clear descriptions illustrated by cases. These studies will offer to many readers a new outlook and render interesting those conditions usually grouped together and described as the "disease" epilepsy, although some will find it difficult to acknowledge many of the conditions mentioned as being epileptic.

The Croonian Lectures of 1925 are presented as a series of five chapters headed "Disorders of Motility and Muscle Tone with special Reference to the *Corpus striatum*". The author attempts to delimit the functions of the *corpus striatum* by a consideration of case material, experimental work and clinico-pathological evidence. The careful consideration of the facts, leading to definite statements of opinion, makes this section easy to read and should clear the minds of many on topics that have tended to become complex and confusing.

Other chapters are on the narcolepsies, pathological laughing and crying, the old motor system and the new, dysaesthesia and their neural correlates, with a final study on the Argyll Robertson pupil.

The volume leaves one with the feeling that the facts have been considered in a careful and authoritative fashion, and is the more satisfying in so far as it is easy and pleasing to read. The writer is particularly interesting in his references to subjective sensations and phenomena, and in the literary quotations with which they are illustrated.

The name of the writer is sufficient commendation to neurologists, who will prize this collected series of papers, but the content and style are such as to render the volume of value and interest to the general physician who wishes a clear statement of modern ideas on the above mentioned subjects.

DAVID SMITH

Clinical Electrocardiography Sir Thomas Lewis, M.D., F.R.S., D.Sc., F.R.C.P., C.B.E. Fourth edition. 128 pages, illustrated. Price 8s 6d. Shaw & Sons, Ltd., London, E.C.4.

This monograph like all the works of Sir Thomas Lewis is a model of concise and clear description. No words are wasted and the subject is clearly stated. The only important addition to previous editions is the section on coronary thrombosis, the latest clinical entity to be added to the list of recognizable heart defects. It is pointed out that electrocardiographic methods furnish diagnostic data of great value. Apart from this, few changes are noted. Here and there a few words are added or omitted in order to give improved elegance of expression to what is already clear.

In these days when electrocardiographic language colours all literature on heart disease the general practitioner is frequently bewildered by the many technical terms. He will find in this monograph exactly what he needs to aid him in interpreting the evidence of heart disease in so far as this special method is concerned.

K. A. MACKENZIE

Practical Surgery of the Abdomen George H. Jull, M.D. Foreword by W. Wayne Babcock, M.D. 1275 pages, 1291 illustrations. Vol. I and II. Price \$17.75 net. F. A. Davis Co., Philadelphia, 1928.

The first thought one has after reading these volumes is the ease and rapidity with which the whole text may be covered. There are two reasons at least, first, the number and excellence of the illustrative drawings throughout the whole work, and second, the simple and lucid English employed. The work is not couched in the language of the professor who often, quite unconsciously, assumes the conventions of the Chair. Rather is it that of the pleasing conversationalist who, with a good conceit of his knowledge, tells how he is doing certain things and how others should be done. There is nothing strained, and a total absence of inhibition marks the literary style of the book.

Were this work confined to an actual description of operations alone it would be almost possible to read it through without the printed text, so rich is it in illustration of every operative step. But it is much more than a work on the mechanics of operations. The pre-operative and post-operative treatment of the patient

are set forth in simple, direct language, and one gets the feeling that an operation is a real trinity in which these elements share equally in importance with the more intensive performance of the operating room. Nor is the psychic side of the patient to be neglected. "Surgeons should treat patients, not diseases," and, consequently, one finds in the pre-operative care some excellent advice directed to the often difficult task of getting the patient's confidence and training his mental reactions into harmony with his environment. Diagnosis, pathology, surgical anatomy, all have their rightful place in the text.

The author's well reasoned conservatism on the subject of pylorotomy will appeal favourably to medical internists and to many surgeons. He rests his case, here as elsewhere, on sound physiological principles, and adds the evidence of much clinical experience to his contention.

If one has to learn operative surgery from a book I know nothing better than this. As an example of the practical simplicity of detail one might mention the chapter on operations on the anterior abdominal wall. It is difficult to call up any abnormality of the different herniae described which is not accounted for, and a proper modification in operative technique is detailed to meet the irregularity. Dr. Juilly's bright volumes like certain luminous bodies, doubtless have their dark specks, but one reading does not reveal them. There is safety in his operative guidance, wisdom in his advice and simplicity in all. It is, therefore, a good teaching book, excellent for students and a great practical aid to the surgeon.

GEORGE H. MURPHY

Text-book of Pharmacology and Therapeutics or the Action of Drugs in Health and Disease. Arthur R. Cushny, M.A., M.D., LL.D., F.R.S. Ninth edition revised by C. W. Edmunds, A.B., M.D., and J. A. Gunn, M.A., M.D., D.Sc. 743 pages, 73 illustrations. Price \$6.00 net. Lea & Febiger, Philadelphia, 1928.

The revision of this excellent text book has been most conscientiously carried out by the joint revisers. The critical and literary flavour imparted to the book by Cushny has not been spoiled and the additions have served not only to bring it up to date as a readable text book of pharmacology, but also to bring it into harmony with the tenth revision of the U.S. Pharmacopoeia. It can be strongly recommended to all members of the medical profession who wish to gain a modern knowledge of pharmacology and useful direction in the therapeutic application of such drugs as may be employed with advantage in medicine. It will furnish also the practitioner with a needed knowledge of the dangers of his materia medica and of toxicology. The book is excellently printed and bound and is a credit both to the publisher and to the authors.

V. E. HENDERSON

An Introduction to Experimental Pharmacology. Torald Sollmann, M.D., and Paul J. Hanzlik, M.D. 521 pages, illustrated. Price \$4.25. London and Philadelphia, W. B. Saunders Co., Canadian Agents, McAmish & Co., Toronto, 1928.

This book is an adaptation of Sollmann's well known Laboratory Guide in Pharmacology. It contains many excellent features which make it a standard book of reference for laboratory workers in physiology and pharmacology and indeed all those who experiment on the living animal. Any young teacher of pharmacology would find in it an excellent source of well thought out experiments for use in his classes.

V. E. HENDERSON

Laboratory Manual of Physiological Chemistry. D. Wright Wilson, Benjamin Rosh Professor of Physiological Chemistry, University of Pennsylvania. 272 pages. Price \$3.50. Williams & Wilkins Co., Baltimore, 1928.

The practical work in biochemistry done by students

at the University of Pennsylvania is outlined in this book. A few experiments, well chosen, are inserted at the beginning, to refresh the student's mind on the inorganic constituents of biological materials, with particular reference to the principles of their quantitative estimation. The relationship of indicators to hydrogen ion concentration is next treated, and this is followed by a few experiments on the physical properties of colloids.

Part I treats of the carbohydrates qualitatively, with experiments on characteristic reactions only. Proteins are considered somewhat briefly, using albumin and globulin mainly as examples. Their properties are considered as one class and little emphasis is placed on separate groups. There are special detailed instructions for the preparation of cystine and tyrosine. The section on the chemistry of fats is particularly well chosen. It includes the best qualitative tests and quantitative determinations of iodine and saponification values.

Part II treats of the body tissues and fluids. The usual experiments on salivary, gastric and pancreatic digestions are given. Milk is examined qualitatively only. A few experiments are described with bone, muscle, yeast and bile. Blood is examined thoroughly, both qualitatively and quantitatively. Urine is treated likewise. There is a short section on the pathological constituents of urine. The volume ends with a few dietary deficiency experiments in outline.

The book is interleaved with blank pages. It represents a thorough course in biochemistry which has been well tried in the laboratory. It further lays emphasis on the essentials, which are not hidden in a mass of experimentation as so frequently occurs.

E. GORDON YOUNG

The Determination of Hydrogen Ions. William Mansfield Clark, M.A., Ph.D. Third edition. 717 pages with charts. Price \$6.50. Williams & Wilkins Co., Baltimore, 1928.

For those familiar with previous editions of this book the fact that a completely rewritten issue is at hand is all the review necessary.

For readers of a journal such as this, for whom, except those engaged in laboratory work, a general knowledge of its subject matter only is needed, the book may look so formidable on first glance as to inspire no further interest. It may be said, however, that there is so much in this volume we all should understand, in view of its importance to medicine, so much that it is possible to understand and enjoy without knowing higher mathematics, that it may be hoped that all our libraries at least will have a copy available.

Although of a more purely technical nature and of an entirely different type this book gives one the same interest that Bayliss', "General Physiology" does. The first few chapters may be read and understood without difficulty, and reading them with their very clear explanations of the foundations on which the work is built, of its theory, terms and methods, should permit a clear grasp of what may at first seem so very abstruse. Then, after having read the introduction to chapter V, who is there who would not wish to read to the end?

The more technical and practical parts are written fully and clearly. After the subject has been carefully led up to, the colorimetric method is defined and explained. The comparative values of the hydrogen and hydroquinone potentiometer and the sources of error are so plainly pointed out that, according to the work to be done, a correct choice of method and instrument should be easily made.

The concluding chapters deal with theory and practical applications with a very full bibliography. The impossibility of giving a complete bibliography seems to be a worry to the author, but that would be a task beyond any one man. Enough is given to enable any one to find what he wants.

C. S. McKEE

Liver and Liver Extracts
in the treatment of
PERNICIOUS ANAEMIA

The specificity of the Minot-Murphy liver diet has been conclusively demonstrated in the therapy of pernicious anaemia. In many cases, however, it proves impracticable to keep patients on a diet rich in liver, but in these cases the oral administration of specially prepared liver extracts will achieve the desired results.

Liver Extract prepared according to a method devised by Cohn and his associates at the Harvard Medical School is available from the Connaught Laboratories, *either as a powder or as a solution*, in packages each of which contains the extract derived from approximately five pounds of liver. It is of equal therapeutic value in either form, but from a practical point of view the powder has certain obvious advantages over the liquid.

*Information relating to the use of Liver
Extract in the Treatment of Pernicious
Anaemia will gladly be sent to any
Physician or Hospital upon request*

X-RAY AND PHYSIOTHERAPY IN THE PRACTICE OF MEDICINE

A keen observer attending Roentgen Ray and Physiotherapy meetings during the last year or two must have noted a circumstance of considerable interest. We are not referring to the remarkable progress in technique in these two branches of medicine, nor yet to the constant increase in the percentage of good results reported. Rather we have in mind the striking number of new names and new faces one meets with at every such gathering. To be sure, the men of great accomplishment who have for years devoted themselves to these newer fields are still seen and heard, and—let us truly hope—will always continue to give us the benefit of their knowledge and experience. Yet alongside of them, in ever increasing number, we see physicians who without attempting to specialize have acquired skill and familiarity with X Ray and Physiotherapy, and with it the interest that leads them to these meetings.

This is indeed an encouraging sign. It well establishes the fact that these fields are regarded today as much a part of medicine as the older forms of diagnosis and therapy. It is a logical development to which simplification of technique, and the consequent high uniformity of results obtained, has largely contributed. Equal share in the credit for it must be accorded modern equipment which has reached an extraordinary degree of perfection. It is difficult to appreciate the extent of the progress made unless you actually compare modern equipment with that available only a few short years ago. Large, cumbersome and often noisy pieces of machinery have given way to compact, smoothly operating and quiet apparatus that no longer require huge rooms to house it, and a combination physician, electrician, engineer and mechanic to operate it.

Instead present day equipment is so soundly and well designed, with such beauty of line, that it represents an asset and an ornament to any office. The perfected mechanisms offer a remarkably high degree of safety, safety to the patient, the operator and the devices themselves. With mechanical perfection has come a notable increase in accuracy, in the precision of these instruments, and a corresponding improvement in results obtained with them. Precision, of course, is of paramount importance, it is only with accurate equipment, where the output can be measured and controlled within the most narrow limits, that results can be assuredly duplicated. It is precision which permits us to lay as much dependence on X Ray and Physiotherapy as we do on other diagnostic and therapeutic means.—*Adv.*

 THE GLASS OF HEALTH

Sheltered Sunshine for Convalescents with

Vita Glass

TRADE MARK

Convalescent patients can seldom be taken outdoors with safety owing to the risk of cold winds and sudden changes of temperature. Many medical men are overcoming this difficulty by the use of "Vita" Glass, which transmits the biological and therapeutic wave-lengths of the ultra-violet rays that ordinary window glass shuts out entirely. "Vita" Glass introduces into the sickroom a gentle, sheltered heliotherapy which acts as a valuable curative agent and a rapid restorative in convalescence. Now that prices have been considerably reduced, medical men may safely prescribe "Vita" Glass for patients of only moderate means. Those interested in "Vita" Glass for their own homes or for their patients are invited to send for authentic information concerning the notable results obtained in Hospitals, Sanatoria, Schools, Offices, Factories and private houses. May we send you authoritative data on heliotherapy and the interesting story of Vita Glass.

◀ ANNOUNCING ▶

Two New Editors of The 1928 Practical Medicine Year Books

GEORGE R. MINOT, M.D., Professor of Medicine, Harvard, Director, Thorndike Memorial Laboratory, Consultant, Massachusetts General Hospital, Chief of Fourth Medical Service, Boston City Hospital, etc

WILLIAM D. STROUD, M.D., Associate in Medicine, University of Pennsylvania, Associate in Cardiology, U of Pa Graduate School, Chief of Heart Clinic, Pennsylvania Hospital, etc

Dr Minot edits the section of the 1928 YEAR BOOK OF GENERAL MEDICINE on "Diseases of the Blood and Blood Making Organs, and of the Kidneys" with the collaboration of William B. Castle, M.D., Assistant in Medicine, Harvard, and Assistant in Thorndike Memorial Laboratory. Dr Stroud has charge of "Diseases of the Heart and Blood Vessels." The other sections are edited, as indicated above, by Drs George H. Weaver, Lawrason Brown and Ralph C. Brown.

Now Ready for the Profession

"**G**ENERAL MEDICINE" now is being delivered to subscribers. So is "General Surgery," edited by Evarts A. Graham, M.D., Professor of Surgery, Washington University, St. Louis. "Eye, Ear, Nose and Throat" will be published within a few days. The other PRACTICAL MEDICINE YEAR BOOKS listed on the coupon will follow at short intervals.

THIS IS THEIR 27TH SEASON OF SERVICE TO THE PROFESSION. MORE PHYSICIANS SUBSCRIBE TO THEM THAN TO ANY OTHER WORKS OF THEIR KIND. THEY ARE STANDARD—THE AUTHORITATIVE ANSWER TO YOUR QUESTION, "HOW CAN I GET THE SALIENT PRACTICAL POINTS OF CURRENT PROGRESS WITHOUT READING THOUSANDS OF PAGES OF PERIODICALS?"

See How These Books Will Help You in Your Practice

YOU NEED NOT ORDER THEM OUTRIGHT. EXAMINE THEM AT OUR EXPENSE. IF AT THE END OF 10 DAYS YOU DECIDE YOU DON'T WANT THEM, RETURN THEM. CHECK THOSE YOU ARE INTERESTED IN AND

Literature on Request

Toronto, Canada

After the Storm

of acute infections, the shock of surgical intervention, there is need of a staff on which to lean during the trying time of convalescence.

A systemic tonic, Guiatonic supplies such a dependable support, and by stimulating general metabolism as well as increasing the hemoglobin content of the blood, it markedly shortens the period of convalescence.

Guiatonic

*A generous trial quantity free upon request William R
Warner & Company, Ltd., Manufacturing Pharmacuetists
since 1856 727 King Street West, Toronto, Ontario*

A palatable preparation of special salts of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. It contains no narcotics.

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

ANÆSTHETICS

CHLOROFORM

PREPARED FROM BRITISH ETHYLIC ALCOHOL

It was this CHLOROFORM which we made for Sir J Y Simpson in 1847 and used by him when he discovered its anæsthetic property and its far reaching benefit to humanity

This CHLOROFORM may be ordered through any Wholesale Drug House in Canada and our Agent

Mr. R L GIBSON
88 Wellington St W.
TORONTO, ONT

IMPORTANT—We can only guarantee Chloroform to be of our manufacture which has stoppers sealed with our trade mark straps

Metchnikoff's Theory of Intestinal Purification and Its Relation to Fresh Yeast

IN commenting on the therapeutic use of yeast, one of the great French physicians said recently

"Yeast reduces the toxins in the alimentary duct which, by penetrating into the blood stream, make the body cells grow old, as demonstrated by the great master Metchnikoff

"By setting itself against the development in the intestines of putrefactive organisms, either introduced by food of bad quality, food badly digested or contaminated, or resulting from intestinal infection, it is the real gendarme of the intestine "

This is striking confirmation by a distinguished foreign authority of the experience of many American physicians and surgeons, who have for years accorded to fresh yeast a definite place in therapeutics. Its gentle yet effective stimulation of peristalsis and its tendency to produce stools of normal bulk and moisture content are also well known and understood

Fresh yeast also stimulates the flow of gastric juice and increases

the patient's appetite and sense of well-being. Unlike cathartics it is non-habit-forming and non-irritating to the intestinal wall. Fresh yeast, as distinct from dried or killed yeast, contains millions of viable, active cells which have been definitely demonstrated to flourish even in their passage through the lower intestine

Physicians generally prescribe three cakes of Fleischmann's Yeast daily, one before each meal or between meals, plain or in water, hot or cold—or any way the patient prefers. For stubborn constipation it is most effective when suspended in hot water (not scalding), before each meal and at bed time

Fresh yeast, being a food, should of course be given regularly and over a sufficient period of time

A copy of the latest brochure on yeast therapy, containing a bibliography of articles and references on the subject, will gladly be mailed on your request. The Fleischmann Dept 472, 208 Simcoe St., Toronto, Ont

FLEISCHMANN'S YEAST IS MADE IN CANADA BY CANADIANS

A NERVE FOOD AND TONIC THAT BUILDS NEW TISSUE

Phospho-Lecithin, Wampole, is Actual
Food for the Nervous System

Contains in most effective combination six elements of proven value as nerve nutriment, Calcium, Potassium and Strychnine Glycerophosphates, Lecithin and Avenin

Phospho-Lecithin, Wampole, is indicated in nervous prostration, nervous debility, sexual impairment, nervous excitement, hysteria, insomnia, and as a restorative tonic after typhoid fever, pneumonia, influenza and la grippe

The Tycos Office Type **Sphygmomanometer**

IN the periodic health examination determination of blood pressure is an important point. The Tycos Office Type Sphygmomanometer because of its peculiar construction renders invaluable service in this work. In addition to accurate blood pressure readings much can be learned of the arterial wall consistency by study of the single systole.

The Tycos Office Type Sphygmomanometer illustrated has a silvered metal dial, long black hand and heavy case. It is designed for use on table, desk or it may be fastened directly to the wall. Its larger size enables much more accurate observation than is possible with the small pocket type model.

The new carrying case makes a convenient method of carrying and storing the Office Type Sphygmomanometer. Makes the instrument available for bed side work.

A Knowledge of Shoes is Helpful to Every Physician

In a recent address to the Medical Profession, a prominent physician deplored the lack of interest being shown by his profession in the treatment of foot ills, and advised every physician to include these cases within the scope of his practice

Diagnosis will often reveal that misalignments in the foot structure are the cause of illness. Let a cuneiform, scaphoid, metatarsal or any one of the twenty-six bones in the foot slip out of its proper position, and a reflex action, sometimes far removed from the feet, will occur

That shoes are the principal cause of modern foot troubles, is conceded. Badly shaped lasts, excessive heel heights, crowding, straining, etc., all borne with a suppressed sigh of pain, can be blamed for fallen arches, crippled toes and various foot deformities which, individually or collectively, upset normal balance, proper posture and good health

When a diagnosis shows that such a condition exists, a change to shoes that provide normal freedom and corrective support is indicated. In the opinion of leading orthopedists who have studied shoes, the Cantilever is ideal for such cases

Cantilever Shoe

(For Women, Men and Children)

Just a few of the scientific features that recommend the Cantilever Shoe (standard models) for foot correction. Adequate support for the arches, a flexible, muscle exercising shank (arch) which fits the foot arch perfectly, combination lasts, correctly balanced heels of moderate height, straighter inside line, room for all the toes, full tread across the ball

The fine quality and good appearance make the Cantilever an exceptional value exclusive of its healthful features

It is no wonder that the physician not only recommends Cantilevers to his patients but wears them for his own benefit

Royal College of Surgeons England

EXAMINATIONS IN CANADA

First Professional Examination for the Diploma of Fellow TORONTO - JULY or AUGUST, 1929*

Arrangements have been completed by the Canadian Medical Association whereby the Royal College of Surgeons of England, will conduct in Canada the "Primary" examination in Anatomy and Physiology leading to the

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

The examinations, both written and *viva voce*, will be held by two examiners in each subject sent from England, and one assessor in each subject who is resident in Canada, but appointed for the purpose by the Royal College

A candidate for examination must deliver to the General Secretary of the Canadian Medical Association prior to April 1, 1929, for transmission to the Secretary of the Royal College of Surgeons, the following certificates

- 1 Of matriculation at a "recognized University",
- 2 Of having completed the examinations in Anatomy and Physiology for degrees in Medicine and Surgery of a "recognized University",
- 3 Of having dissected in a "recognized" Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a "recognized" Medical School

- 4 Of having attended in a "recognized" Medical School or Schools —
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall individually be engaged on the necessary experiments manipulations etc but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
- (e) a course of Histology

The fee for examination or re-examination shall be \$100 00

The Final Examination for the Fellowship is held only in England and candidates for admission to that examination must have passed the Primary Examination and hold the Diploma of Member of the Royal College of Surgeons of England or have held for not less than four years a degree of a "recognized University" registrable on the Medical Register of Great Britain.

This is a non profit making organization, ensuring the lowest rates. For full information as to rates etc., and an illustrated pamphlet address the secretary

A. M. WALLER,
47 Sun Life Bldg. Hamilton

DISCOURAGED WOMEN

Dysmenorrhea, or irregularity, are notoriously difficult to treat and often the physician contents himself with prescribing a sedative or some emmenagogue. It is surprising, though, what results can be achieved, even in obstinate cases by the use of a rational combination having both local and general tonic effect. Hyperol presents such a combination. Ethical, non secret, it represents a prescription that will appeal to every experienced physician. Its advantage over the extemporaneously compounded one, lies in the quality of the drugs used, the standardization of quality and skill in manufacture, its unvarying potency. Full information, case reports and test supplies will be mailed to physicians requesting them on their letterheads. The Purduo Frederick Company, 135 Christopher Street, New York City

THE FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION

No. 1, Wimpole Street, London, W. 1.

with which is associated some 50 General and Special Hospitals in London, is prepared to offer the following facilities to qualified practitioners

- I General Courses are arranged covering all branches of Medicine and Surgery. These Courses occupy the student for several hours every day and last for two weeks.
- II For post-graduates requiring less intensive study, comprehensive tickets are issued admitting them to the ordinary hospital practice (general course)—ward-rounds, out-patient departments, operations, etc. These tickets permit the post-graduate to make out his own time-table to suit his requirements and all information can be obtained at the office of the Fellowship. The approximate fees are as follows: 1 week \$10, 2 weeks, \$15, 1 month \$26, 2 months \$47, 3 months \$63, 6 months, \$94, and 1 year \$105.
- III Special Courses are arranged at the Special Hospitals associated with the Fellowship, and these permit of intensive study in one specialty for a period ranging from 1 week to one month.

The Special courses arranged for the coming months are —

JANUARY

Cardiology	Jan 14 to Jan 25—National Hospital for Diseases of the Heart. All day. Fee £7 7s 0d (limited to 20).
Diseases of Children	Jan 14 to Jan 26—Queen's Hospital. All day. Fee £3 3s 0d.
Medicine, Surgery and the Specialities	Jan 23 to Feb 9—Prince of Wales's General Hospital Group. All day. Fee £5 5s 0d.
Psychological Medicine	Jan 29 to Feb 23—Bethlem Royal Hospital. Tues and Sats 11 a.m. Fee £1 1s 0d.

FEBRUARY

Gynaecology	Feb 11 to Feb 23—Chelsea Hospital for Women. Mornings and/or afternoons. Fee £5 5s 0d.
Dermatology	Feb 11 to Mar 9—St John's Hospital. Every afternoon. Fee £1 1s 0d. (Practical Pathological Demonstrations arranged. Fee £4 4s 0d.)
Diseases of the Chest	Feb 25 to Mar 2—Brompton Hospital. All day. Fee £3 3s 0d.
It is hoped to arrange later a course in Diseases of Children	February/March—The National Hospital, Queen Sq. (8 weeks)
Neurology	

MARCH

Orthopaedics	Mar 11 to Mar 23—Royal National Orthopaedic Hospital. All day. Fee £3 3s 0d. Minimum of 10.)
Ophthalmology	Mar 11 to Mar 23—Royal Eye Hospital. Afternoons only. Fee £1 1s 0d.

Copies of all Special course syllabuses and of the General Course Programme may be obtained on application. The Hospitals reserve the right to make any alterations necessary in dates and fees. Post graduates are advised, therefore, to make early enquiry.

Special weekly Clinical Demonstrations in Medicine, in Surgery and in Ophthalmology arranged from October to July.

The Clinical Demonstrations and the Lectures are open to all members of the Medical Profession without fee.

Post graduates may become Members of the Fellowship of Medicine and Post Graduate Medical Association, the annual subscription is \$2 50, which includes the subscription to the monthly *Post Graduate Medical Journal*. Subscription to the Journal only \$1 50. Every effort is made to assist Members to obtain the post graduate work they require.

McGILL UNIVERSITY

MONTREAL

FACULTY OF MEDICINE

The regular course of study leads to the degrees of M.D., C.M. Double courses
leading to the degrees of B.A. or B.Sc. and M.D., C.M. may be taken

In addition there are

Advanced courses to graduates and others desiring to pursue special or research
work in the laboratories of the University or in those of the Royal Victoria and Mon-
treal General Hospital

A practical course of lectures of from six to twelve months duration to graduates
in Medicine and Public Health Officers for the Diploma of Public Health

A course in Dentistry leading to the degree of D.D.S.

A course in Pharmacy for the Diploma in Pharmacy (this course satisfying the
requirements of the Pharmaceutical Association of the Province of Quebec)

The Matriculation Examinations for entrance are held in June and September of
each year. Full particulars of the examinations, fees, courses, etc., are furnished by the
Calendar of the Faculty, which may be obtained from

THE SINGLE ARC AUTOMATIC LAMP

PROMPTED by
a desire to
maintain its

leadership in the field of carbon arc lamp production and to offer customers the best and most complete line of professional therapeutic lamps, BRITESUN, INC., is pleased to announce a handsome new carbon arc modality, the new BRITESUN SINGLE ARC AUTOMATIC LAMP

This is a lamp noteworthy for its efficiency, dependability, economy and wide therapeutic range

The arc is struck automatically as soon as the current is switched on and no attention is necessary while the lamp is burning. The use of 12 inch, 10 millimeter carbons minimizes loss of time and delay and gives a maximum continuous burning period of three and one half hours

Ease of adjustment is an outstanding feature. A smoothly operating counter-balanced arrangement permits adjustment of the head and reflector to any

desired position. The stand and upright can be moved in a complete circle without moving the base due to a specially designed swivel mechanism. The lamp is mounted on a black crystalline base which rolls on three ball-bearing rubber tired casters.

The new BRITESUN Single Arc Automatic Lamp is a most versatile source of light. By the use of the various types of Eveready (National) Sunshine and Therapeutic carbons, a complete balanced spectrum or any desired range of the spectrum can be produced. The Sunshine carbon produces a spectrum which duplicates natural sunlight. Other types of carbons produce a maximum of the long wave length Ultra Violet, or a maximum of the

short germicidal wave length. The Infra Red carbon produces visible and the long wave infra red

Price Complete

\$135.00

Further particulars regarding this convenient and efficient lamp will be gladly furnished on request without obligation

Your Patient will Enjoy Outdoor Living in the Land of Sunshine This Winter

THROUGH the window or from the terrace your patient will see an unfolding panorama of mountains, desert plains, a meandering river in a fertile valley. El Paso and Juarez, largest cities on the border, airplanes in trans-continental flight. They may look across to Old Mexico, land of enchantment and mystery—and they may visit this land for six cents carfare.

Sun-kissed distances give a breadth of view and a cheerfulness that is indispensable to sufferers from respiratory diseases.

El Paso is 800 miles from the sea, east or west, 3,762 feet above sea level. Humidity averages 37% lowest for any weather station of record. Rainfall is less than 10 inches a year. Mean annual temperature is 63.5 degrees; winters are mild. There are 331 sunshine days a year—sunshine 82 out of every 100 hours the sun can shine.

El Paso is a metropolitan city with every comfort and advantage. Excellent sanatoria, convalescent homes, superior housing for patients, families. El Paso has a cordial western welcome for your patient and charming southern customs too. A remarkably high percentage of tuberculosis victims get well in El Paso.

McKesson Universal Unit No. 100

The McKesson Gas-Oxygen Machine

is not limited to the amount of pressure it can deliver to the patient

The McKesson machine not only regulates the pressure of mixed gases delivered to the patient, but in addition, it maintains that pressure and mixture, and furthermore stops the flow of gases when that pressure is secured, thus preventing any escape or waste of gas due to the accumulation of too much pressure

The McKesson machine is most simply controlled, since one screw, namely the pressure screw, regulates the pressure at which the gases are delivered into the inhaler, and only safe pressures may be administered

Other unique features are the emergency valve for artificial respiration, the automatic valves, which regulate the intermittent flow of the gases, and the re-breathing attachment which prevents the elimination of too much carbon dioxide from the blood

Physicians' and Surgeons' Supplies
TORONTO MONTREAL

To quote an eminent authority on ultraviolet therapy:

"WITH regard to apparatus, there is no lamp which emits heat, light, and ultra-violet rays of every wave length. Different lamps give different selections of all three.

"The lamp which I recommend is the mercury vapor lamp. Its output is rich in ultra-violet rays but poor in heat rays. It gives off no fumes. It is a clean, cold lamp. It works automatically, needing very little attention. Patients feel no warmth when under it, and they may complain of chilliness during treatment, especially in the winter months, unless the room is adequately warmed. A lamp of full size should be chosen. Small lamps are not of much use."

—E P CUMBERBATCH
M.B. D.M.R.E. M.R.C.P.

From a paper read before the Southport Division of the British Medical Assn. March 30, 1928. (British Med. Jour. July 14, 1928)

Reprint No. 587 of the above article in full will be sent on request

THE Uviarc burner, as used in all Victor Quartz Lamps, is the result of long and intensive research. It produces a large quantity of ultraviolet radiations in proportion to the electrical input, with a consequently low cost of operation. It operates consistently and without atten-

tion for hours at a time. No special wiring required—simply plug in on the lighting circuit. That is why the installation of a Victor Quartz Lamp represents real economy in the

long run, and gives the utmost satisfaction to thousands of physicians and institutions the world over.

The scientific advances in ultraviolet therapy, and its widespread adoption in the leading clinics in recent years, are coincident with the availability of the mercury vapor arc in quartz.

A New EPHEDRINE NASAL SPRAY

for promoting

Sinus Ventilation and Drainage

EPHEDRINE INHALANT, Swan-Myers contains 1% solution of Ephedrine alkaloid in light mineral oil, colored for identification and fragrantly perfumed with oil of rose

It contains no aromatics, such as menthol, thymol, camphor or eucalyptus which frequently irritate and sting. Patients experience no discomfort from the cold air after the use of this spray. Applied as an oil spray, or as drops in the nose, this Inhalant will contract capillaries, reducing swelling of the turbinates and diminish hyperemia. It promotes sinus ventilation and drainage. Its action is prompt and sustained.

For Complemental Feeding

Prescribe **DRYCO** *The Safe Milk*

MANY pediatricists advocate regular complemental feedings for the breast fed infant. They find that this relieves the strain upon the mother, prolongs the nursing period and has an excellent effect upon the weight and general nutritional condition of the child. Such a procedure also minimizes the difficulties attendant upon eventual weaning.

Dryco is ideal for use in conjunction with breast milk. The special drying process renders the formation of thick, tenacious curds impossible, eliminating digestive and nutritional disturbances. Free from pathogenic bacteria, the use of Dryco avoids milk-borne infections.

LET US SEND SAMPLES, SUGGESTED FEEDING TABLES AND CLINICAL DATA!

THE DRY MILK CO. - - 15 PARK ROW, NEW YORK, N. Y.

When the Colon Bacilli Revolt

Some intestinal enemies
1 Streptococci 2 Bacillus typhosus 3 Crigia hominis 4 Entameba coli 5 Entameba histolytica A shows ameba containing remnants of ingested red blood cells

WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxemia resulting from constipation and fecal impaction, the consequences may be grave in the extreme

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fecal impaction, and in certain forms of intestinal toxemia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL, the original mineral oil—agar-agar emulsion

A generous trial quantity
sent on request

WILLIAM R. WARNER & CO., LTD

Manufacturing Pharmacutists since 1856

727 KING ST. WEST

TORONTO, ONT

Agarol is the original Mineral Oil—Agar Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification, stability, pleasant taste without artificial flavoring, free from sugar, alkalies and alcohol, no oil leakage, no griping or pain, no nausea, not habit forming.

The Long Night of the Far North

DURING the long Arctic night man survives stiffening cold because he knows how to protect himself. Not only does he wear thick furs but, in his limited dietary, fats predominate, affording him not only fuel for body heat but the needed Vitamins A and D as well.

In our winter months, with the fog, smoke, short days and minimum of sunshine, we need these same Vitamins A and D to fortify our body requirements during the various periods of stress that arise.

Cod Liver Oil is especially needed in winter as an accessory food

Prescribe "Standardized Cod Liver Oil, P D & Co."

It contains in each fluid ounce not less than 13,500 Vitamin A units and 3,000 Vitamin D units. It is as nearly tasteless as a pure cod-liver oil can be.

In 4-ounce and 16-ounce bottles

IMPORTANT to PHYSICIANS ESPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponda Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician but lacerations leucorrhoea gonorrhoea prolapse post-operative and post-confinement treatment, and uterine hemorrhage are some of the conditions in which Ponda Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponda Tampons.

Ponda Tampons are packed in six tampons to a box and are made in the following medication

Back of Every Pain..

is a disturbance in the physical or mental equilibrium, an interruption of some vital function, a deviation from the normal. Injuries, inflammations, excessive muscular strain, disturbances of the circulation, all are productive of pain. And be it trivial or severe, prolonged or ephemeral, uppermost in the mind of the patient is the prompt suppression of that pain.

To the patient racked by the painful pneumonic process, nothing is more grateful or comforting than an Antiphlogistine jacket applied over the thoracic walls. Physicians conversant with this simple procedure generally concede that this plastic anodyne dressing increases the superficial circulation by the induction of artificial hyperemia setting up a highly decongesting process in the deeper seated tissues and thereby relieving the dyspnea and the stress on the right heart.

Doctors the world over are more and more coming to recognize the unique properties of

Antiphlogistine

as an invaluable auxiliary in the management of the pneumonias or wherever pain is a prominent factor.

Formerly with the Carnegie Nutrition Laboratory 1908-1920

Lessen the monotony of Liquid and Soft Diets with appetizing dishes prepared from Knox Sparkling Gelatine

Since a liquid diet is usually used to give maximum nutrition with the minimum tax on the digestive tract, its foods must be concentrated and without solid particles. Here Knox Sparkling Gelatine is of great value. Not only does it help to vary the liquid and soft diets in a most appetizing and satisfying way, but it also supplies essential elements of nutrition. It is easily digested and absorbed and has a food value of about 120 calories for each ounce.

In diabetic diets, Knox Sparkling Gelatine is useful in increasing protein value and in imparting a sense of satiety. In infant feeding, because of its ready assimilability, nutritional value, anti-regurgitative effect and pleasing flavor, gelatinized milk is being used by a number of pediatricists. From numerous tests, Downey has determined that the addition of gelatine increases the available nourishment of the milk mixture by about 23%.

Knox Sparkling Gelatine is pure—unbleached, unflavored, unsweetened. From raw material to finished package every process is under constant chemical and scientific control. No human hands touch Knox Sparkling Gelatine at any stage of its manufacture.

*Write for booklets
by foremost dieticians*

These have been prepared by the highest dietetic authorities. They explain the uses of Knox Sparkling Gelatine in various illnesses—offering a number of appetizing recipes that will help vary the prescribed diets. Surgeons, doctors, dieticians and members of hospital staffs will find they contain much valuable information. The coupon is for your convenience.

CAUTION!

All gelatines are not alike. Many have added acid, flavoring and coloring matter. In the form of ready prepared desserts, they contain as high as 85 per cent carbohydrates.

Knox Sparkling Gelatine is a protein in its purest form, particularly suitable where carbohydrates and acids must be avoided. It contains more than 80 per cent pure protein (4 calories per gram).

Specify Knox when you prescribe gelatine and you will protect the patient from brands unsuitable for his dietary purposes.

KNOX GELATINE LABORATORIES,
453 Knox Avenue, Johnstown N.Y.

Please send me, without obligation or expense the booklet which I have marked. Also register my name for future reports on clinical gelatine tests as they are issued.

You can find no purer, finer ginger ale, nor one so pleasing to patients

This fine old ginger ale has a mild, mellow taste which wins the most laggard appetite. Its subtle, gingery flavor appeals to patients and its carefully balanced carbonation produces that tingle of goodness and stimulation which makes for a pleasing change in the sickroom.

What is more, "Canada Dry" proves particularly useful in overcoming the nauseous sensation after an ether anæsthetic. It is refreshing and stimulating. It goes a long way toward putting the patient in the right frame of mind for getting well.

Of course you can safely prescribe "Canada Dry." We maintain our own resident buyer in Jamaica so that every chain of ginger bought comes up to our high standard. We control the entire manufacturing process and make our own ginger extract so that we may be positive no inferior ingredients are used.

Then, the ingredients are blended and balanced under laboratory methods of exactness and purity. Hourly tests are made to check up on those proportions and purity. The water used in "Canada Dry" is completely soft. It is purified before using by the violet ray process. "Canada Dry" is uniformly carbonated by a secret method.

There is no capsicum in this fine old ginger ale. It does not bite the tongue or leave an unpleasant after-effect. Many physicians prescribe it for that very reason. Many hospitals always have it on hand. You may safely consider "Canada Dry" if a carbonated beverage is indicated.

"CANADA DRY"

Made in Canada by Canada Dry Ginger Ale Limited,
Toronto, Edmonton and Montreal.
Formerly J. J. McLaughlin Limited, and Caledonia
Springs Corporation Limited.

OLD AGE DEFERRED

Stimulates metabolism

Increases muscle tonicity

Raises respiratory exchange

Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands, after their extirpation from healthy animals.

.

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

Dose One or two tablets three times daily

CONTRIBUTIONS

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this *Journal*.

COPYRIGHT Matter appearing in the *Journal* is covered by copyright under the Copyright Act of 1921, but, as a general rule, no objection will be made to the reproduction in reputable medical journals of anything in these columns, provided proper credit be given

MANUSCRIPTS: Should be typewritten, double spaced, and the *original* copy submitted to the respective Editorial Boards

ILLUSTRATIONS Will be paid for by us when satisfactory photographs or drawings are supplied by the author. Negatives are not acceptable. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct and preferably black and on glazed paper, drawings should be made in india ink on white paper. For illustrations requiring cuts the best copper plate is used and all are printed on glazed paper. The *Journal* reserves the right to return photographs which are not satisfactory. Contributors are respectfully requested to limit illustrations to such as are absolutely necessary.

REPRINTS TO CONTRIBUTORS These may be ordered from the printers upon the form submitted with the galley proof

ADVERTISEMENTS

First advertising forms go to press thirty days in advance of the date of issue. In forwarding copy, time must be allowed for setting up and submitting proof. Advertising rates on request.

N.B.—We exclude from our columns all known questionable advertisements and appreciate notification from our readers relative to any misrepresentation.

CLASSIFIED ADVERTISEMENTS are payable in advance. To avoid delay in publishing, remit with order. Advertisements under the following headings cost \$2.00 for each insertion of 40 words or less, additional words 5 cents each.

WANTED: Apparatus, Assistant, Books, Location, Partner, Partnership, Situation

FOR SALE: Apparatus, Practice, Sanitaria, Drug Stores

At the Menopause

The distressing symptoms that so often accompany the climacteric, but more particularly the aggravated symptoms of the artificial menopause, are frequently controlled by the administration of

LUTEIN TABLETS, H W & D
LUTEIN SOLUTION AMPULES, H W & D.

The choice of the medication depends, of course, on the judgment of the physician as to whether oral or hypodermatic administration is indicated. Both products represent the

CORPUS LUTEUM OF THE SOW

unmodified by treatment with solvents or by exposure to temperatures above animal body heat in the drying process. All separation of extraneous matter is made by mechanical means and all drying is *in vacuo*. The unaltered *corpus luteum* should, therefore, be presented in our products and clinical experience with them should demonstrate their therapeutic activity.

Ovarian dysfunction as evidenced in dysmenorrhea and amenorrhea is also an indication for Lutein medication, and if the diagnosis of such dysfunction is reasonably well established, definite therapeutic results may be expected.

WHOLE OVARY TABLETS, H W & D
OVARIAN RESIDUE TABLETS, H W & D

are also offered for those who prefer, for certain indications, the use of the whole gland or of the residue remaining after corpus luteum separation. *Literature furnished on request*

The Long Climb Back

from the physical and mental depletion of acute respiratory diseases will be noticeably and agreeably shortened by the administration of Guiatonic. A true restorative, it stimulates and activates and may be prescribed freely, without fear of deranging the most delicate digestive tract.

Guiatonic

A generous trial quantity free upon request William R Warner & Company, Ltd, Manufacturing Pharmacutists since 1856. 727 King Street West, Toronto, Ontario

A palatable preparation of special salts of gualacol and creosote which may be freely given to the weakest patient without fear of gastric disturbance. It contains no narcotics.

Indicated in all depressed or debilitated conditions, or whenever a tonic is required

OVALTINE

and the Milk Diet

"Ovaltine" relieves the monotony of the milk diet

It increases the food value by fifty per cent

It is an effective agent for adjusting the carbohydrate deficiency of milk

The accessory food factors are present in "Ovaltine" in correct nutritive ratio and greatly enhance the nutritional value of milk.

Ovaltine" renders possible food concentration in small volume, a valuable feature in conditions of difficult alimentation

By the action of its malt constituent the dense heavy curd of cow's milk is converted into light, flaky, easily digested coagulum, and it has been conclusively shown by laboratory experiment that "Ovaltine" increases the digestibility of milk two fold

"Ovaltine" is a highly concentrated extraction of malt, milk and eggs. One cupful when made as directed has a greater food value than 3 eggs or 12 cupfuls of beef extract

A liberal supply sent free for clinical trial on request

"The Line Test" In Infant Feeding

*I*F medicine had been born a complete science, if the law of variation could be suspended, it is conceivable that the sum and total of human knowledge could be encompassed in a single volume, the science of medicine could consider its conquests complete and its responsibilities for further research ended.

But this is not the case. Exceptions constantly appear, the old order is found to possess its limitations, necessity, the mother of invention, provides another and still greater urge. So finality is always in the offing—the last word is never spoken.

It was the recognition of the law of variation that prompted the assertion that each infant is a law unto itself and feeding must be adjusted to its individual needs. Even then, exceptions arose, they still arise and from these necessities, progress in the art of infant feeding and science in the preparation of infant diet materials emerges.

Resources are valuable only as they are assembled to serve greater and ever varying ends. To exercise his own resources to their fullest extent, to enjoy the selective principle with the utmost freedom, the physician demands a latitude in the choice of dietary materials at his disposal, just as infants demand a wide variation to suit their needs.

This then, is the test, not a single product, but a *line* of infant diet materials that increases the range and scope of the physician's skill just as it increases our alertness and zest to serve his needs.

Dextri Maltose—A highly assimilable carbohydrate for cow's milk modifications.

Recolac—A reconstructed milk for traveling or where the milk supply is faulty.

Casec—The principal protein of cow's milk, for the correction of fermentative diarrhoea.

Cod Liver Oil—Standardized as to potency, produced exclusively from Newfoundland Cod.

Protein Milk—Now available in a form that is boilable for a 10-minute period.

Malt Soup Stock—For use in cases of an idiosyncrasy against carbohydrate.

Lactic Acid Milk—Uniform in composition and acidity, flows freely, no curds.

Florena—A wheat flour especially useful for Butterflour or Butter Soup Mixtures.

Powdered Milk—Clean milk of known origin, tuberculin tested, low bacterial count.

Royal College of Surgeons England

EXAMINATIONS IN CANADA

First Professional Examination for the Diploma of Fellow

TORONTO - JULY or AUGUST, 1929*

Arrangements have been completed by the Canadian Medical Association whereby the Royal College of Surgeons of England, will conduct in Canada the "Primary" examination in Anatomy and Physiology leading to the

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

The examinations, both written and *viva voce*, will be held by two examiners in each subject sent from England, and one assessor in each subject who is resident in Canada, but appointed for the purpose by the Royal College

A candidate for examination must deliver to the General Secretary of the Canadian Medical Association prior to April 1, 1929, for transmission to the Secretary of the Royal College of Surgeons, the following certificates

- 1 Of matriculation at a "recognized University",
- 2 Of having completed the examinations in Anatomy and Physiology for degrees in Medicine and Surgery of a "recognized University",
- 3 Of having dissected in a "recognized" Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a recognized Medical School.

- 4 Of having attended in a "recognized" Medical School or Schools —
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall individually be engaged on the necessary experiments manipulations etc but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
- (e) a course of Histology

The fee for examination or re-examination shall be \$100 00

The Final Examination for the Fellowship is held only in England and candidates for admission to that examination must have passed the Primary Examination and hold the Diploma of Member of the Royal College of Surgeons of England or have held for not less than four years a degree of a "recognized University" registrable on the Medical Register of Great Britain.

* The exact date will be announced on this page in later issues

MULFORD
DIAGNOSTIC
TEST CASE
No 60

To Facilitate Correct Diagnosis

THE Mulford Test Case No 60 contains 72 specific Proteins in dry powder form for identifying hay fever, asthmatic or other forms of protein sensitiveness. It provides every facility for making diagnostic tests conveniently and accurately.

You can make these tests without previous experience.

The reactions, in conjunction with the history of the case and a knowledge of the local conditions, will help you in planning the course of treatment.

If the offending pollen or protein cannot be avoided, desensitizing treatment with gradually increasing doses of the specific Mulford Pollen or Protein Extracts may be employed with success in a large majority of cases.

Mulford Pollen and Protein Tests are also supplied in single cutaneous test outfits and 25-test vials.

Hanovia makes an Important Contribution to the Science of Ultra- Violet Light Therapy

Pertinent Facts About the Entire Quartz Mercury Anode Type Burner

- 1 Stability of the arc
- 2 No excessive heat
- 3 No fumes or smoke
- 4 Requires no adjustments
- 5 Operates without attention
- 6 Low cost for operation
- 7 Technique easily standardized
- 8 No danger from sparks
- 9 Maximum treatment at minimum cost
- 10 Saves time

A means for accurately measuring light dosage "THE GORDON ULTRA-VIOLET METER"

THE Quartz Mercury Vapor Lamp has been, from the beginning, a standard source of ultra-violet rays. And to say that the Quartz Lamp has always been a standard source of ultra-violet rays is virtually equivalent to naming the Hanovia Quartz Lamps—the Alpine Sun and the Kromayer. For Hanovia Lamps were the first

practical artificial source of ultra-violet rays.

Now with this newly perfected Gordon Ultra-Violet Meter, we are provided with a dependable and convenient instrument for use in the hospital, clinic, or physician's office — at once replacing crude chemical methods and the more involved procedure of the physical laboratory.

ON

THE DUTY OF THE PHYSICIAN IN THE PRESENCE OF ECLAMPSIA*†

By CYRILLE JEANNIN, M D

Professor of Obstetrics in the University of Paris

Paris

ECLAMPSIA exists and will always exist in spite of the closest observation and the repeated examination of our patients. Its manifestations break out with disconcerting suddenness, and it is truly a terrible disease. The fact that the maternal mortality reaches 25 per cent and the fetal mortality 50 or even 70 per cent will indicate the great importance that this subject has for the practitioner.

When confronted with a patient whom one thinks to be the subject of eclampsia there are three important questions to ask oneself, and these questions will form the subject matter of this address:

1 Is it really a case of eclampsia? 2 What is the gravity of the particular case presented? 3 What course of action should be taken in the case in question?

I IS IT REALLY A CASE OF ECLAMPSIA?

This question may present itself for answer at three different times: (a) before the appearance of the attack, (b) during the attack, and (c) in the comatose period that follows the attack.

An important point is that an accurate diagnosis be made early, for it often enables the practitioner, by his conduct of the case, to prevent the onset of the attack. How can a positive

diagnosis be made before the appearance of the convulsive seizure? By the study of the prodromal features.

The prodromata are most particularly observed in primiparæ, but multiparæ may also manifest them. They appear most often during the last three months of pregnancy, not in those who are the subjects of chronic albuminuria or who have been treated for this affection, but in women who have not had albuminuria except for a few days or perhaps even for a few hours. Sometimes a very definite cause can be made out, such as an alimentary intoxication, exposure to cold, or overwork.

The study of the prodromata may be divided into four main groups, according to the way in which they manifest themselves.

Urinary apparatus. Albuminuria may appear in a very fulminating way, the quantity of albumen often rising very quickly to thirty or forty grammes, at other times increasing steadily for some days. The quantity of urine as a rule tends to be reduced, and this feature may be very pronounced. Such urine is always very dark and occasionally may be frankly bloody.

Circulatory system. Hypertension is a symptom, the highest point reaching often 20 or 25, or even more. Edema is extremely variable. It may affect the lower limbs, the upper limbs, sometimes may be absent, but is rarely lacking in the face.

Nervous system. The patient has a constant

* Delivered at the annual meeting of the Province of Quebec Medical Association at Sherbrooke, September 18, 1928.

† Published simultaneously with its appearance in *L'Union Médicale du Canada*. Translation by A. G. N.

and generalized headache. She complains of sleeplessness at night and somnolence during the day, she may even be somewhat stuporose. She suffers from trigeminal neuralgia, particularly affecting the ophthalmic branch of the nerve, she manifests sensory disturbances, notably visual, and ringing in the ears.

Digestive system. Vomiting is a constant prodromal symptom, and Chausnier has well described the epigastric pain, as like a bar, which has caused his name to be given to this particular sign.

The duration of these prodromal features is essentially variable, from a few hours to several days, and sometimes they are almost lacking. In certain cases, as the result of a treatment that abolishes the symptoms, these prodromata constitute alone the whole disease. This is the condition that Bar has called "eclampsisme." During this period, in order to make a differential diagnosis, it is necessary to distinguish uræmic crises from the simple alimentary intoxication due to digestive disturbances.

When you are in the presence of a patient undergoing a convulsive seizure diagnosis is easy, owing to the fact that the attacks are always characteristic.

Let us study first the positive case. The diagnosis will be summed up in the description of the attack, which develops invariably in three phases. The first phase is that of *invasion*. The woman suddenly manifests contractions of the face which last only a few seconds. The second phase is that of *tonic convulsions*. These convulsions are generalized throughout the body, the muscles of respiration only excepted, and have a variable duration of from six to ten seconds. The third phase is that of *clonic contractions*. In this phase it is above all the muscles of the sub-diaphragmatic region of the body that are affected: the upper limbs "beat the recall", the lower limbs remain immobile. The duration of the convulsions is about thirty seconds, which seem interminable hours to those around, for the patient is labouring and seems to suffer so much. In making the differential diagnosis one must eliminate (1) the epileptic seizure, during which the patient always voids clear urine, (2) a hysterical attack, which can be excluded by the disorder of the convulsions and the absence of all signs of disturbed function, and (3) a uræmic attack, which is often confused with eclampsia, but this error does not signify, for the treatment is the same. It is necessary,

in all cases which have to do with eclampsia, to take cognizance during the whole course of the disease of the hypertension, of the scantiness and dark colour of the urine, of the enormous amount of albumen in the urine.

In the presence of coma you will agree that there is no character pathognomonic of the eclamptic form. It will be necessary to base your diagnosis upon the history, the albuminuria, the scantiness of the urine, and the hypertension. You should remember to differentiate eclamptic coma from that of diabetes, alcoholism, uræmia, and from cerebral hæmorrhage and hetero-intoxication.

II WHAT IS THE GRAVITY OF THE CASE?

One must keep clearly in mind two most important ideas when it is desired to estimate the prognosis in eclampsia. Eclampsia is a very serious accident, a "malady of surprise," and a surprise of a disagreeable order, using the phrase that Tarnier used to delight in repeating to his pupils. One should always and in every case guard the prognosis for the mother, and especially for the fetus. However, cases can be differentiated, and one should weigh the several factors, such as, the time of onset of the eclampsia, the number of seizures, the coma, the urine, the hypertension, the temperature, and any complications that may arise, before one can estimate the outcome in a definite way.

When eclampsia appears in a woman but little advanced in pregnancy the case is always most grave, if the seizure comes on at the moment of labour the prognosis will be less serious than if earlier in the pregnancy, if the seizure occurs just subsequently to delivery the outlook is better, if the accouchement has preceded the attack by some hours the prognosis is still better.

When the patients have had from one to ten seizures one-quarter of them die, when they have had ten to twenty, one-third die, when more than twenty, one-half succumb. However, there are exceptions, for patients may die after the first or second attack, and the number of attacks always indicates the degree of severity, so that the prognosis should be guarded accordingly.

When the patient is in a state of coma the gravity is in proportion to its duration, if the coma is prolonged it involves a fatal issue.

The quantity of albumen that is present in the urine is not a valuable guide in the establishment of the prognosis. It is, rather, oliguria or anuria that are the grave factors, particularly if the

urine remains bloody. On the contrary, one would take a more favourable view in the presence of a urinary crisis. Polyuria is one of the good features, as it shows that the kidneys are eliminating satisfactorily.

Hypertension is always of unhappy augury, especially when it remains high, or rises again after bleeding.

Hyperpyrexia presents always a grave character, and the prognosis will be still more guarded in such a case.

Finally, the complication with icterus or cerebral hæmorrhage is always of grave import. The psychoses, which are generally of late appearance, are of little interest. Acute mania, however, can occasion considerable disorder, and melancholia often becomes chronic.

III WHAT PROCEDURE SHOULD BE ADOPTED?

I come now to the question of treatment, which is, without doubt, the matter that most interests the physician in general practice. The treatment is of two orders, it is *prophylactic*, and it is *curative* or *symptomatic*.

As soon as albuminuria appears in a gravid patient you should be on the look-out for eclampsia. Every day you should check in these cases the amount of urine discharged, the amount of albumen per litre, and the arterial tension. Should any of the symptoms appear, you should institute immediately a milk or even a water diet, rest in bed should the albumen be more than 0.50 centigrammes per litre, protection from the cold by means of warm clothing and flannel bands, and venesection if there is hypertension.

In spite of the most careful surveillance of your parturient patients there will be some who develop signs of eclampsia unexpectedly and you must treat them. In the prodromal period, before there has been a convulsive seizure, everything must be done to prevent one. There should be absolute rest in bed, a diet of lactose and water, a drastic purge, venesection if indicated by hypertension, which may enable you to avert the seizure. If in spite of this treatment the symptoms increase, you should bring on labour, provided that the woman is near term and that the child is viable. When a seizure threatens you can sometimes avert it by chloroform anæsthesia. The patient should be prevented from biting her tongue or otherwise injuring herself. Between the convulsive attacks the treatment will be variable, either medical, or obstetrical, or, exceptionally surgical.

Medical treatment consists in lessening arterial tension by repeated bleeding, the intoxication of the patient should be lessened by a fluid diet, and by the injection of glucose serum to favour diuresis, finally, the nervous system must be quieted. Keep the patient in a dark room, remote from noise, forbid all visits except those of the nurse in charge. Prescribe small enemata of chloral, and in cases of great agitation you may be forced to administer sedatives in the form of morphine or opium.

The obstetrical treatment comes to the fore when the woman is in labour. Then, at all costs, the delivery should be accomplished as quickly as possible. On the contrary, when the woman is not yet in labour, when the fetus is not viable, and when the eclampsia is mild, it is clear that you should wait and be satisfied with medical treatment. Interfere only when the fetus is viable, when the eclampsia seems serious. In such cases the procedure of choice, in the interest as much of the mother as of the child, is the vaginal Cæsarian section.

The surgical treatment concerns almost without exception the specialist in urology, and is employed only in cases of anuria. Here decapsulation of the kidneys, or nephrotomy, is indicated.

Once the convulsive phase has passed, it is your duty to watch the patient very narrowly while in coma, in order to prevent her from falling out of bed. A water diet should be maintained at least for forty-eight hours, then allow a little milk and later a purely milk diet, until you can note that a urinary crisis has occurred and that there has been a considerable diminution in the albuminuria, when a vegetable regimen may be instituted.

CONCLUSIONS

Eclampsia is easy of diagnosis, all that is required is to note the quantity of urine passed in twenty-four hours by the patient with albuminuria, and to take the arterial tension frequently.

Eclampsia always involves a very serious prognosis and one often difficult to establish. It must be remembered that it is a "malady of surprise," and the surprise is of a disagreeable kind. As a complication it may come on in the late period.

Everything should be done to prevent the onset of convulsions. Here venesection plays an important role.

An Address

ON

THE VALUE OF PERIODIC HEALTH EXAMINATIONS*

BY A. GRANT FLEMING, M.B.

Montreal

THE desire to escape from sickness and to achieve health is not a new one. No man ever wished to suffer from disease, and history records how mankind has evaded and fought disease as best it knew how.

We are today in a very enviable position as compared with the ancients. We have the knowledge which, if we would use and apply it, could cut in half the amount of sickness that now occurs in our country, thus greatly reducing human suffering, and the needless expense and other undesirable companions of sickness. Our increase in knowledge has made us feel rather superior. We smile with pity upon those who believed in the supernatural cause of disease, in witchcraft, the healing power of the King's touch, the influence of the evil eye, and the relationship between the stars and disease. But are we superior? Could there be any greater ignorance, in the light of present-day knowledge, than that displayed by those who still deny that successful vaccination prevents smallpox, or who, if they do not deny it, fail to practise it, which amounts to the same thing. There are those who quibble also about the value of pasteurization as a means of making milk supplies safe. The present will assuredly seem absurd when it becomes historical.

In seeking an explanation to account for illness and death from preventable diseases and for the lack of health, we find that two of the chief factors are ignorance and laziness.

Health, it must be understood, implies not only freedom from disease, but a one hundred per cent development of the capacity of the individual. Doctor Donald B. Armstrong has defined health in these words—"The vigorous, beautiful, smooth-running efficient operation of mind and body, of the instincts and the will, in a harmony of purpose and accomplishment."

It is rather remarkable that so few attain com-

plete health, when we consider that beyond question, health is such a desirable possession—desirable, not in the sense that health in itself is an end in life, but rather because, as a condition of life, it makes possible achievements and happiness in work and play that without it are unobtainable. Health is therefore good both for the individual and for the community.

The modern public health movement grew out of a humane desire to lessen the human misery which had resulted from the industrial revolution. It was directed, at first, almost entirely to the improvement of living and working conditions—sanitation as we now call it. There were added later isolation and quarantine, i.e., the control of communicable diseases.

People, in general, will agree as to the need for pure water, for safe milk and pure food, and will even support the principle of quarantine, the latter, however, perhaps, with the mental reservation that it applies to the other man's home and family. In other words, we favour those measures which improve things for us, providing that they call for no personal effort. So it is that those health measures which ask for nothing from the individual, excepting money, for their provision and enforcement, come about and are carried on successfully. After all, taxes for health work are just as painless as any other taxes.

This sort of community health work does a great deal to protect citizens from disease that is carried by milk, water and food, and it does control, to a considerable extent, the communicable diseases which are spread from one human being to another. It has limitations, however, and it makes very little contribution towards the positive ideal of health, the one hundred per cent development of the physical and mental capacity.

Individual health depends essentially upon the individual's practice of what we call "personal hygiene." Even in our age of organization, we expect that we must consider our bath, our bed-

* Delivered at a public meeting of the Canadian Medical Association, Charlottetown, June 21, 1928.

time, and our open bed-room window as personal responsibilities. Modern inventions have given us conveniences that greatly assist and make reasonably easy the practice of personal hygiene. The opposition that followed the introduction of the first bath-tub on this continent, in Cincinnati in 1842, leads us to believe that bathing was not a very generally accepted practice. One can hardly doubt that since the bath-tub has become a common household fixture, its use has materially increased.

Children may practise hygiene because of parental discipline, or the stimulation of personal pride, or the competitive spirit of the group, as seen in such organizations as the Junior Red Cross.

As adults, we practise personal hygiene chiefly as an established habit carried from childhood, and continued, largely, because we have found that it makes us more comfortable. We continue to raise our bed-room window at night, not in the interest of health, but because we have found that we are more comfortable, that we feel better in the morning after having slept in a well-ventilated room. We know that if we do not wash our hands before eating, we are uncomfortable during the meal. This, I believe, is most encouraging. We may expect the majority of people to practise personal hygiene because they will like it because it will make them feel more comfortable. I do not believe we can ever expect that any considerable number of persons will do things they do not like just for the good of their own health, still less for the good of others. Most of us are as self-centred as the man who, according to the old doggerel, prayed —

"God bless me and my wife,
Our John and his wife,
Us four and no more Amen"

There is given to us, in the periodic health examination, an opportunity to secure a larger percentage of health. The periodic health examination by the family physician offers something that is not to be secured in any other way.

There is no lack of general health advice. Such advice is good and is valuable within limitations. Its value is limited because it is general. Of those who read it, or who hear it, many fail to see or understand the personal implication or the need for personal application. While none of us denies the desirability of health, so long as we feel well, so long as we can continue to participate in our favourite pleasures, we are

apt to think that such general health advice does not apply to us, but that it is intended for someone else.

It is desirable that everyone be accurately and fully informed concerning this most important subject of health. The value of such information depends upon its practice. One may know all about the human body, the causes of disease, and the maintenance of health, but unless this knowledge is put to work and made part of the daily life of the individual, it will be useless so far as protecting that individual is concerned. To know that fresh air and sunshine are good is only of academic interest to the person shut up in a dark room, it is of practical value when the window is opened, or when he goes outside. This is a very obvious example, and yet it is one which we see every day. While their number is decreasing, there are still thousands of people in our country who sleep in bed-rooms with windows tightly closed, at least, in winter. There are still many who shut the sun out of their homes rather than fade a carpet, although all of these have doubtless heard of the value of fresh air and sunlight. Most of us are just as foolish with regard to some one or other of the rules of personal hygiene. In most cases, it is because we have not understood or appreciated why these rules must be applied to our individual life. We need to have this pointed out to us, we need to be periodically checked up on it, and that is exactly what the family physician will do in the periodic health examination.

There has been a great reduction in mortality during the past few years, with the result that the average expectancy of life has been markedly increased. But because the reduction in mortality has been chiefly in the younger age group, there has been but little increase in life expectancy for those of forty years of age. This has not happened by chance. It is for the one simple reason that health conditions amongst children have received a great deal of attention in most places, and the reduction in sickness and deaths amongst infants and children has been in proportion to the work done. Look back over the health record of any city, and you will see written in the vital statistics, a remarkable story. After a number of years with the same high infant death-rate comes a period of rapid decline. You seek for the reason and you find two things. First, the establishment of well-baby clinics where mothers are taught the care of their babies, and second, the safeguarding of the milk

supply. The extent and rate of the reduction in infant deaths depend upon the extent and thoroughness of these two efforts. This infant hygiene work is a striking example of the use of knowledge. It is available for any community but it must be used if lives are to be saved. Simply to know about it, to talk about it, means nothing in the saving of lives.

The insidious beginnings of disease are not recognized by the sufferer. They are allowed to progress to serious conditions before the need for medical care is evident. It is left to the layman to determine the need for such care. If every person were examined each year, the earliest signs of disease would be detected, it would be possible to recommend the early treatment which always offers the best chance for cure. If not for actual cure, at least the arrest of the progress of the condition. Many mothers understand this, and infants are taken to private physicians and to well-baby clinics when they are apparently well. In schools, the well child is examined. This is, of course, what the adult should do. When well, try to keep well!

Even at the present time, with all the general information that has been disseminated, the percentage of tuberculosis cases who come to their physician with the disease well-advanced is appalling. The cancer case loses his chance of cure because he has waited to decide that he needs medical advice. The heart case, because of delay in securing advice, loses the chance of early care which would permit, in many instances, of his leading a full, if somewhat restricted, life. There is a great deal of truth in the observation that the man who lives longest is the one who, early in life, discovers that he has some abnormality, and so lives a careful, hygienic life. Is it not reasonable to say that during the period when proper treatment offers so much the oppor-

tunity for revealing the need for such treatment should not be lost, and is it not rather absurd to ask the layman to decide upon the need for treatment during the early period of disease, when it is most difficult to diagnose?

The discovery of defects or of early disease is, however, the lesser value of periodic health examinations. Although a large percentage of apparently well individuals will be found with physical defects that require treatment, with early symptoms of disease whose cure or arrest depends upon prompt action, it is the need for advice concerning the maintenance of health that is the more important point. There are very few who do not need personal advice in the matter of diet, exercise, rest and relaxation, elimination, and other phases of personal hygiene. There are few who might not have better health than they now possess. We are all different, and just what one needs, what another neglects, and what still another abuses, are the things that must be discovered and regarding which advice must be given. This type of advice needs behind it the same scientific knowledge and thought as does the prescribing of remedies for the acutely ill.

The family physician, because of his knowledge of economic, social, and home conditions, and because confidence is reposed in him, is the best qualified for this service.

Amongst limited groups of adults, the need for, and the results of, periodic examinations have been proved. Life Insurance Companies have found it good business to pay for such examinations for their policy-holders. The opportunity is open to all to safeguard their lives, to attain greater efficiency, by securing for themselves a periodic health examination.

Make periodic health examinations an axiom of your lives!

Anti-Mouth-Breathing Mask—This is a device for keeping the mouth closed after operations for producing an adequate airway. A wax impression is taken of the lower half of the patient's face. From this a cast is made. From the cast a thin metal mask is modelled. This fits accurately the lower half of patient's face from the lower margin of the anterior nares to below the chin. Suitable holes are drilled in the metal. These

enable a lint lining to be tacked on and two thin elastic bands attached. The mask is held in position by these elastic bands, which are fixed to a head band of stout webbing by means of "hooks and eyes". The mask has been used by exhibitor for the past six years and found very efficient.—T. B. Jobson, M.D., *Proc. Roy. Soc. Med.*, 1928, *xxi*, 1798.

SMALLPOX VACCINATION*

By R. D. DEFRIES, M.D., D.P.H., AND N. C. MCKINNON, M.B.,

Toronto

IN 1796 Edward Jenner introduced the practice of vaccination. His first vaccination consisted in rubbing into a tiny scratch on the arm of an eight-year old boy a little cow-pox material, taken from a vesicle on the hand of a dairymaid who had contracted the disease in milking cows suffering from cow-pox. In the widespread use of vaccination which followed, several methods for obtaining supplies of vaccine were employed. The most popular, which continued in general use until practically the close of the nineteenth century, was to collect the vaccine from the arm of a previously vaccinated person at the time that the vesicle was well developed. To provide for emergency supplies, crusts from previous vaccination lesions were collected and stored. These methods of "arm to arm" vaccination, although efficient, were open to serious criticism. (Some of the common objections to vaccination as raised by anti-vaccinationists to-day are based on these old practices, these persons continue to reiterate the possibility of transmitting disease by vaccination, but such a danger existed only when the old methods were employed.) Later, calves were used to propagate the virus and the vaccination of children in large numbers at one time was made possible in special stations provided for this purpose. In these stations the vaccinations were performed by the direct transfer of the vaccine from the vaccinated calf to the arms of the children.

Negri in 1842, instead of inoculating cows with vaccine material collected from human beings, inoculated cows with natural cow-pox and transferred the vaccine from cow to cow in series. By 1865 vaccine was produced by animal vaccination in a number of countries but this method was not employed in England until 1881. Following the findings of English Royal Commission in 1896, "arm to arm" vaccination was replaced officially by the use of "bovine" vaccine. In addition to direct vaccination from the

vaccinated areas in cows, the "lymph," so-called, was preserved by drying on small pieces of wood, bone or celluloid, which afforded a convenient means for distribution. The preparation of these "vaccine points" consisted simply of rupturing the vesicles, after a superficial cleansing of the surface, and, by means of a small brush, transferring the vesicle contents to the "points" of bone, wood or celluloid. After drying, the points were ready for distribution. Obviously no bacteriological control could be exercised on vaccine prepared in this manner and the method was subject to this criticism. In 1891 Copeman made a most important advance in the preparation of vaccine by establishing the use of glycerin as a diluent. This permitted not only of much greater production, as the lesions of the calf could be scraped thoroughly and the collected pulp ground in glycerin, but also of bacteriological control of vaccine. It was shown that glycerin serves as a good preservative of the virus and at the same time, in the course of some weeks, destroys extraneous bacteria. With its use, vaccine could be kept until bacteriological examination showed it to be free from pathogenic organisms. At the same time sterile glass capillary tubes as containers for the glycerinated vaccine were introduced into general use. During the following years other antiseptics, including phenol, have been found to be of additional value in the preparation of vaccine.

Extensive bacteriological studies have been made during recent years of the glycerinated vaccine and tests have been established which ensure to physicians vaccine, not only free from all pathogenic bacteria, but at the same time of high potency.

PREPARATION OF VACCINE VIRUS

Vaccine virus is prepared now in commercial quantities by the use of healthy calves, which are carefully selected and are kept under observation for eight days before being vaccinated. Tuberculin testing is carried out as a routine measure during this period of observa-

* Department of Epidemiology and Biometrics
School of Hygiene and Communicable Diseases, University of Toronto

tion and every precaution is taken to make sure that only healthy calves are used

The calf vaccination is performed in the following manner. First, the calf is clipped and the whole body is cleaned by scrubbing with warm water and soap. It is then placed on a suitable table in such a position that the entire abdominal area and inner side of the thighs are exposed. These areas are prepared for vaccination by shaving off the hair and thoroughly cleansing the skin with soap and hot water followed by washing with sterile water, drying, and the application of 95 per cent alcohol to the entire surface. The surgically clean skin is protected at once by sterile towels. The area is further protected from contamination by covering all other parts of the body of the calf, including the legs, with clean cotton. At this stage the calf is moved into an adjoining room which may be spoken of as the operating room and in which the actual vaccination is performed. This consists of making a series of light scratches as close together as possible over the whole abdominal area and inner side of the thighs. It is important that the scratches should not be made deep enough to draw blood. As in human vaccination, the best results are obtained if the scratches are lightly made and just sufficient to break the skin. Vaccine virus is now applied and rubbed into the scratches by using a smooth instrument, such as an ordinary ebony spatula. The vaccine used is usually spoken of as "seed"* vaccine and it is appreciated that special care must be exercised in its preparation.

After vaccinating, the area is protected until the surface is thoroughly dried and the calf is then placed in a special stall or room where it is kept scrupulously clean, excreta being at once removed and every precaution taken to prevent the contamination of the vaccinated area. In the Connaught Laboratories, it has been found of advantage to spray the vaccinated area daily with a 1 in 500 solution of brilliant green. When the vaccine vesicles are fully developed, usually in six days, the calf is washed, then chloroformed and exsanguinated.

The vaccinated area is repeatedly washed with warm water until the superficial crust material is softened and entirely removed. This is an essential step in the preparation of a vaccine of low bacterial content. The pulp, so called, is now removed by using a spoon curette. A post-mortem examination is made of each calf and if evidence of any disease is found the pulp is discarded. The next step consists in emulsifying this pulp by grinding with a 50 per cent solution of sterile glycerin containing 0.5 per cent of phenol, in the proportion of one part of pulp to four parts of glycerin-phenol solution. The emulsified pulp, or as it can now be called glycerinated vaccine, is stored at about zero, centigrade, until distributed. During this time potency tests are completed. This period of "ripening" requires usually from one to two months.

During this period bacteriological counts are made at regular intervals and if the vaccine has been prepared under proper conditions, the bacterial count rapidly falls. Tests are made to detect the possible presence of tetanus or of any other pathogenic bacteria. These tests are made by suitable methods of culture of the vaccine emulsion and by inoculation of guinea pigs, both with broth cultures and with the vaccine emulsion itself. As a result of the action of the glycerin and phenol during the period of storage, in a vaccine which has been propagated and collected under proper conditions, the contaminating bacteria are so reduced in number that often several capillary tubes must be cultured before the presence of a single organism is shown.

It is essential also that the potency of the vaccine be carefully determined, not only before it is distributed, but at regular intervals for a period of three months after its distribution during which time, if kept in a refrigerator, the vaccine should give satisfactory results. If evidence is found in the laboratory that the vaccine so stored is becoming weak the vaccine is recalled. The potency of the vaccine is determined by vaccinating rabbits with various dilutions. A vaccine giving a good "take" (a strong confluent reaction) when diluted with saline in the proportion of 1 part of vaccine to 250 parts of saline is considered to be of satisfactory potency. Confirmatory evidence may be obtained by observ-

* In reference to the source of the seed virus used on this continent, Dr. W. H. Park, Director of the Bureau of Laboratories, Department of Health, New York City, has stated that it is probable that this virus is the strain originally brought to America in 1874 from the Vaccine Establishment of the Local Government Board of Great Britain.

ing the percentage of "takes" in a group of children not previously vaccinated

When the vaccine has been shown to be of satisfactory potency, of minimum bacterial content, and free from possible pathogenic organisms, it is filled into sterile capillary tubes. These tubes are examined, sealed and packaged, care being taken that during this procedure the vaccine is kept cold. As a final precautionary measure a number of tubes out of every filling are tested bacteriologically before the tubes are released for distribution.

TECHNIQUE OF VACCINATING

Any rational opposition to vaccination to-day can be attributed largely to the technique used by some vaccinators and to improper after-care. Jenner in his original description of vaccination, stressed the necessity for avoiding unnecessary trauma. During the nineteenth century, when vaccine was limited in quantity and of uncertain potency, vaccinators introduced long incisions and multiple abraded areas into the practice of vaccination. Thus, there developed the methods of abrading or cross-hatching of from two to four areas of skin varying from one-quarter to one-half inch in diameter. The resultant "takes" were accompanied by many sore arms. Support of these methods was obtained from certain statistical data and the duration of immunity was considered to be dependent on the size and number of scars. More recent work, however, of both experimental and statistical nature, has shown, firstly, that the duration of the immunity is not dependent on the amount of scar, and secondly, that most of the severe reactions and complications are due to unnecessary trauma in vaccinating. In fact, the size of a scar indicates usually the amount of secondary infection, rather than the degree of immunity. The importance of these observations is being recognized only slowly. Although in Germany cross-hatching was discredited and its use forbidden as early as 1897, this method is still practised to some extent even in Canada. Modern methods of vaccination practically eliminate severe reactions, secondary infections, and large scars.

The best time to vaccinate is in the first year of life because the general reaction to vaccination at that time is much less than later. The infant, as a rule, shows no evidence whatever of

reaction, beyond the local lesion. In addition, the site can be kept at rest, clean and dry, conditions which are ideal for a vaccination to run a normal course. It is, of course, unwise under ordinary circumstances to vaccinate any child or adult showing fever or other symptoms of illness.

The immunity following vaccination is not necessarily of a permanent character. This fact was established as early as 1805. Re-vaccination is, therefore, essential. The time at which re-vaccination becomes necessary naturally depends on the duration of the immunity. As school children who have been vaccinated in infancy frequently give reactions closely resembling typical takes, it is evident that the immunity following a primary vaccination may not last longer than a few years. Various estimates have been made of the duration of this immunity but the frequently quoted period of seven years must be considered only as an average period. There is among individuals a wide variation in the duration of the immunity. Some persons present typical takes on re-vaccination within one or two years after a primary vaccination, whereas the majority of individuals retain their immunity for a much longer period. The immunity following a second successful vaccination is probably of longer duration than that following a primary vaccination. There is, however, ample evidence from clinical experience with smallpox in recent epidemics that even one vaccination performed in infancy has protected individuals to some degree when exposed to virulent smallpox many years later. This is shown by the fact that in the Windsor, Ontario, epidemic of 1924, although 32 persons died from this disease out of 67 who were attacked, not one death occurred among those who had ever been vaccinated. On the few vaccinated individuals who developed the disease, the attack was greatly modified in severity, even though only one vaccination had been performed many years previously. Since no accurate estimate can be made of the duration of immunity, re-vaccination with potent virus affords the only means of determining the immunity status of an individual. As a general rule, vaccination in infancy should be followed by re-vaccination early in school life and again at the occurrence of an epidemic.

The best site for vaccination is the arm above the insertion of the deltoid muscle, because this

part can be most conveniently kept clean, dry, and at rest, and is not liable to injury or irritation. These conditions are not obtained as readily on the leg which, as a vaccination site, has other disadvantages in its circulation and lymph drainage.

Numerous modifications of the established methods have been suggested during the past few years. These methods have the common objective of reducing to a minimum the amount of trauma in vaccinating, and, by so doing, avoiding unnecessary reaction with the formation of large scars. The methods outlined below are representative of the modern technique and are widely used.

The Short Scratch — Cleanse the site with soap and water, alcohol, or ether, and allow it to dry thoroughly. Using a sterile needle, make three short scratches from $1/16$ to $1/8$ of an inch in length, about the size of the printed comma on this page, the scratches separated from each other by $1\frac{1}{2}$ inches.

These three scratches are most conveniently arranged at the points of a triangle as shown in the accompanying diagram. Wipe the capillary tube of vaccine with an alcohol swab and allow it to dry. Break

off both tips without contaminating the broken ends of the main portion, and push one end into the rubber bulb until the diaphragm within the bulb is punctured. Expel the vaccine on the two upper scratches (2-3). One capillary tube contains enough vaccine for both. Gently rub the vaccine into the two scratches with the side of the needle. Allow sufficient time for the vaccine to dry. The lower scratch serves as a "control" the value of which will be appreciated in interpreting the vaccination reactions.

The Puncture Method — Cleanse the site as previously described. Holding the sterile needle parallel to the arm, push the point into the skin for a distance of about $1/16$ inch at a point on the arm corresponding to the lower angle of the triangle as indicated in the diagram. This is the "control puncture." Now, on the sites on the arm corresponding to the two upper angles (2 and 3) of the triangle in the diagram,

place a drop of vaccine. Holding the needle parallel as before, push the point through each drop into the skin for a distance of about $1/16$ of an inch. It is essential that the needle be held practically parallel and not at right angles to the arm, and that the point of the needle enter just between the skin layers. The vaccine may now be wiped off. Some vaccinators prefer to make two or more punctures through a single drop.

The method of using a short scratch ($1/16$ inch) at one place and a puncture at another, separated by one and one-half inches, has been found a very useful combination. Controls for each should be made first.

The question may be asked as to the reason for recommending that two vaccinations be made as a routine procedure either by scratch or puncture, or one scratch and one puncture. The answer to this is that failure to "take" is more often reported when only one scratch, or more particularly when one puncture, has been used. Failures in vaccination are due often to the vaccine being of a reduced potency or actually inert as a result of prolonged storage or exposure to heat in transportation. To overcome this possibility of failure it is wise to make two vaccinations, as the chance of failure is reduced and the probability of a successful take is increased. The arm of an infant on account of its small size, should usually be subjected to one vaccination only. Revaccination should always be performed by vaccination in two areas. Especially is this important at times of an epidemic.

The short scratch method gives a very high percentage of "takes," the local reaction is of minimum size and the final scar does not exceed $1/4$ of an inch in diameter. By making two scratches sufficiently far apart, the two lesions do not coalesce even in primary vaccinations and the healing proceeds as quickly as if only one area had been vaccinated. In making the scratch before the application of the vaccine, the vaccinator is able to control better its length and depth. This is a distinct advantage. Objections which are sometimes raised to this method are due to the lack of appreciation of the actual size of the scratch described, namely, $1/16$ to $1/8$ of an inch in length. Thus, the measurement of scratches supposed to be of the proper size shows that

these are often from $1/4$ to $1/2$ of an inch in length

The puncture method gives a reaction and final scar very similar to that of the short scratch. It has not given, however, in our experience, as high a percentage of takes. An increased percentage of takes is obtained by making two or more punctures through a single drop, (that is, the multiple puncture method) but this increases, too, the size of the individual reaction and thereby defeats an aim of modern technique, namely, to have a minimum reaction. The occasional failure with the single puncture method is due either to the fact that the needle point has not satisfactorily entered the skin or that the virus used was of reduced potency. When a fully potent vaccine is used, single puncture vaccination will probably give as high a percentage of takes in primary vaccinations as a short scratch. As vaccine, however, is often of reduced potency due to storage and untoward conditions, it is evident that a higher percentage of takes may occur with the scratch method as this method gives an opportunity for more virus to enter.

The puncture method elicits better an "immediate" reaction on re-vaccinations. This will be discussed later. For these reasons there are advantages in vaccinating by a short scratch in one area and by a puncture in a second area, separating the two vaccinations by $1\frac{1}{2}$ inches. The two small individual lesions, even in primary vaccinations, give rise to no more general reaction than does one, and, as has been said, do not coalesce but heal as quickly as one small area and much more quickly than a large area.

AFTER CARE

The essentials in the after care of vaccination are that the area be kept clean and dry and that there be no interference with the circulation or with the normal evaporation from the area. Anything which interferes even in the slightest degree with either of these produces conditions favourable to secondary infection. The best condition is therefore obtained when no dressing is used. Even clean gauze, pinned on the inner surface of the sleeve, if not actually required, may serve only as a source of irritation. In cases where the vaccination cannot be kept clean without a

dressing, a sterile gauze dressing may be applied loosely to the arm. Adhesive plaster or shields of any description, should be sedulously avoided. Clinical and experimental investigation has shown that the vaccination lesions under such dressings, due to interference with the circulation and evaporation, tend to increase to the whole size of the area covered and conditions become ideal for secondary infection. Even when adhesive is employed to fasten gauze, only narrow strips should be used to fasten the corners of the dressing. These should be placed diagonally across the arm, rather than around it, and at some distance from the vaccination. If the lesion ruptures and serum exudes, sterile gauze should be applied to the site with the precautions indicated. Complete rest is indicated when there is fever, headache, malaise, or other symptoms of a general reaction.

VACCINE REACTIONS AND THEIR INTERPRETATION

In addition to the characteristic "take" following vaccination two other reactions are recognized following re-vaccination. These two reactions have been described as the immediate reaction or the reaction of immunity, and the accelerated or vaccinoid reaction. One of the underlying factors which determines the character of the reaction following re-vaccination is the degree of immunity possessed by an individual. It is obvious that the previous history of an individual regarding successful vaccination or smallpox should be taken into consideration in interpreting the reactions. A primary vaccination, if successful, results in a typical take. A re-vaccination, if successful, shows one of four reactions which can be classified according to the time when the lesion reaches the height of its development. The possible reactions are (a) A typical "take" as in a primary vaccination. (b) An immediate reaction. (c) An accelerated reaction. (d) A combination of (b) with either (a) or (c).

Typical "Take"—A typical 'take' is the only type of reaction which results from a primary vaccination. It may, however, occur after re-vaccination in individuals who have lost their immunity. The examination of the vaccinated area within forty-eight hours shows no evidence of a reaction beyond that seen on the control scratch or puncture. On the third

day slight redness can usually be seen at the vaccination site. On the fourth day a small papule is evident and the redness is more definite. On the fifth day, or occasionally earlier, the papule has changed to a small shallow vesicle surrounded by a narrow but clearly defined red zone, the primary areola. During the following days the vesicle increases in size, the contents become more turbid and a central depression, which appeared early, shows commencing crust formation. Between the eighth and the twelfth days, a second zone of redness appears outside the primary areola and remains in evidence for some part of a day. Though larger, it is much less clearly defined than the primary areola. This zone, spoken of as the secondary areola, marks the height of the reaction. Practically coinciding with the development of this secondary areola, a general reaction frequently occurs in adults and older children, as shown by fever, malaise and headache. The axillary glands are palpable and tender. (During this time the patient should be in bed.) The absence of any general reaction in infants is a very strong point in favour of infant vaccination. Following the fading of the secondary areola, the lesion rapidly retrogresses, being covered with a dry crust. In about two weeks' time the crust falls off leaving a depressed scar. If a typical "take" does not occur the correct procedure is to repeat the vaccination with fresh virus, and, if this fails, to repeat the vaccination a third or even a fourth time. Complete natural immunity is very rare. For cases which prove repeatedly resistant to vaccination, as performed either by the scratch or puncture method, intra-dermal vaccination may be used. In this method, the contents of one capillary tube of vaccine virus are expelled into the barrel of a 1 cc syringe. The plunger is inserted and 0.5 cc of sterile saline is drawn into the syringe. The vaccine material is thoroughly mixed with the saline by shaking and an injection of 0.1 cc is then made intra-dermally. The reaction which follows is a typical "take" and the resultant scar is about 1/4 of an inch in diameter.

Immediate Reaction—The immediate reaction is seen only in persons previously successfully vaccinated or in those who have had smallpox. It is characterized by the formation within

twenty-four hours of the time of vaccinating of a definite red papule accompanied by itching. This reaction reaches its full development within seventy-two hours and rapidly retrogresses. It never develops into a vesicle but quickly resolves from the papule stage. Comparison of the vaccinated site with the control scratch or puncture is essential in interpreting this reaction. The reaction is generally larger and more definite when re-vaccination is performed by the puncture method than by the scratch method. It is usually interpreted to mean that the individual has a satisfactory immunity to smallpox, but too great reliance must not be placed on this interpretation. It has been found that occasionally a person may give an immediate reaction which is later followed by the development of a vesicle, indicating that the individual did not possess as high a degree of immunity as would be interpreted from an early reading of the reaction. A more important point in this connection is the fact that dead or inert virus can elicit immediate reactions in persons previously vaccinated or in those who have had smallpox. In this lies a danger that immediate reactions, elicited by virus inert or incapable of producing a typical "take," may be interpreted to mean that the individual is immune to smallpox, thus giving a false sense of security. If potent virus had been used in these persons, reactions approaching a typical "take" might have been obtained.

The Accelerated Reaction—The accelerated reaction is seen in individuals who have lost some of the immunity induced by a previous successful vaccination or by an attack of smallpox. Beginning before the fourth day, this reaction progresses further than the papule of the immediate reaction and may pass through the vesicle, pustule and crust stages, occasionally resulting in a small scar. It reaches its height after the third day, but before the tenth day. It may vary, therefore, in its character and the time of development, from a reaction closely resembling an immediate reaction, to one closely resembling a typical "take." Its progress through all the stages however, is rapid and the lesion seldom reaches the size of a typical "take." In many instances the lesion of an accelerated reaction is dying before a typical "take" would have reached its height. This

reaction is seen, as stated, in individuals who have been previously successfully vaccinated or have suffered an attack of smallpox and who, through the lapse of time, have lost a part of their immunity. It indicates, therefore, a lessened immunity.

Although the more or less arbitrary time limits given here cannot be applied exactly to every case, there is little difficulty in placing observed reactions in one of these classes. As the immediate reaction may reach its height before the third day, it is necessary that observation of a re-vaccination should be made about the second or third day. A second observation of the site should be made about the sixth day when the presence of an accelerated reaction or a typical take may be recognized. The absence of any reaction following a re-vaccination requires that the procedure be repeated with known potent vaccine. The vast majority of "no reactions" following re-vaccination, however, are due to lack of observation at the proper time, rather than to the lack of the occurrence of reaction.

COMPLICATIONS

Complications are of rare occurrence if the modern methods of vaccinating are employed and the vaccinated area is kept clean and dry, shields and other unnecessary coverings being avoided. Armstrong, in a study of experimentally induced infection of vaccinations in monkeys, has shown conclusively that shields and other coverings produced conditions favouring secondary infection, and that, when tetanus spores were added to the vaccine used, tetanus developed only in the monkeys which had the vaccinated areas covered. To our knowledge, no authenticated case of tetanus following vaccination has ever been reported in Canada. Other complications, such as impetigo, the transfer of vaccine to other parts of the body, cellulitis and erysipelas, are of rare occurrence, as shown by the extensive experience during recent years of many public health officers in Canada. Encephalitis following vaccination has been described in other countries, but in spite of extensive investigation, the claim that the vaccine was the cause has not been substantiated.

HOW TO KEEP VACCINE VIRUS

Vaccine virus must be kept in a well-iced refrigerator. Studies have shown that even at the temperature of a "cold" cellar or in a "cool" window vaccine virus rapidly loses its potency. Failures in vaccination and the necessity for repeating the procedure are for the most part due to weak or inert vaccine. As the vaccine is carefully tested and is known to be of satisfactory potency when it is sent out from the laboratory, it follows that the loss of potency must be caused by exposure to heat either in transit, in the drug store, or in the physician's office. To protect the vaccine when it is sent in quantity, special refrigerator boxes, which are kept filled with ice by the express companies, are used for shipping. A few packages, however, sent to a physician cannot be so protected in the mails and in consequence the vaccine may be rendered completely inert by contact of the mail bag with steam pipes or other sources of heat in the winter or by exposure to the heat of summer. A potent vaccine should give successful results in at least 90 per cent of primary vaccinations. The obtaining of a smaller percentage of "takes" in primary vaccinations should be sufficient warning to the physician that the vaccine was not fully potent, and it should be appreciated that the failure to "take" was not due to any natural immunity, but to weakness of the vaccine. In this connection it should be remembered that even "dead" virus may elicit immediate reactions in re-vaccination where typical "takes" or accelerated reactions might occur if the virus were fully potent. The use of weak virus may, as stated, give rise to serious error in the interpretation of the immunity status of individuals. If the vaccine cannot be kept in a well-iced refrigerator, it is desirable that fresh supplies be obtained as required from time to time for immediate needs only, rather than that vaccine be used which has been kept for even a few weeks under less favorable conditions.

VACCINATION CERTIFICATE

A vaccination certificate to be of any value should state the day on which the vaccination was performed, the day on which the vaccination was observed, and the character of the reaction, whether a primary "take", an immediate reaction or an accelerated reaction. A less complete statement leaves room for serious error. The

certificate should bear the signature of the person vaccinated in order that quarantine officers or other persons interested may have some means of proving that the bearer of the certificate is the person to whom the certificate was originally issued. Comparison of the bearer's signature with that on the certificate is used for this purpose. A copy of a suitable certificate is given herewith.

CONCLUSIONS

1 Modern methods of preparation of vaccine virus assure a product of high potency and freedom from all pathogenic organisms

2 Modern methods of vaccination eliminate severe reactions and large scars

3 The short scratch method, the puncture method, or a combination of these is advocated

4 Shields or other unnecessary coverings are a source of danger

5 Primary vaccination should be observed about the seventh day. Re-vaccination should be observed about the second or third day, and again about the fifth or sixth day

6 Temperatures higher than that of a refrigerator are destructive to vaccine virus, and the use of virus not kept in an ice-box may lead to error

7 A vaccination certificate should state specifically the type of reaction observed

DESCRIPTION OF PLATES]. (See page 532)

In these plates the vaccinations shown have been performed by the short scratch method and by the single puncture method for the purposes of comparison of the resultant lesions. In each instance the short scratch vaccination appears on the left of the picture and the single puncture vaccination on the right hand side.

PLATE I shows photographs of approximately actual size of a typical "take" in an adult. On the fourth day the small though definite vesicle is to be noticed. By the eighth day the vesicle has increased, surrounded by a definite primary areola. In the centre of the vesicle a crust has formed. The picture of the tenth day shows the reaction at its height. The indefinite, large secondary areola is well shown. The picture taken two months after vaccination shows the actual size of the final scar. Little difference is noted in the development of the lesions produced by the two methods of vaccination employed.

PLATE II shows the actual size of an immediate reaction in an adult with a history of a previous successful vaccination and re-vaccination. The reaction following the puncture vaccination (right hand side) is somewhat larger and more definite than that produced by the short scratch vaccination, illustrating the observation made in the text. The control scratch and puncture can just be seen about an inch above and corresponding to the reactions. The contrast between the reactions and the control is readily seen.

PLATE III shows an accelerated reaction. On the fourth day the puncture lesion is slightly more in evidence than the scratch lesion. By the fifth day more reaction has occurred on the scratch vaccination and there is evidence of some vesicle formation. The eighth day shows both lesions larger but already drying, in contrast to the growing vesicle of the primary "take" on the same day.

PERIARTERITIS NODOSA*

WITH THE REPORT OF A CASE

BY G. F. STRONG, M.D.,

Vancouver

AT the present time periarteritis nodosa is one of the clinical rarities of medicine. First mentioned by Rokitsansky in 1852, the name and first accurate description of this disorder were given by Kussmaul and Maier in 1866. Since that time there has been a slow accumulation of authentic cases. In the first forty-two years, to 1908, only twenty-six instances of this peculiar disease were reported,¹ whereas in the last twenty years one hundred and sixteen cases, including the present report, have appeared. This increasing incidence may indicate a greater interest in the disease and a more careful study of autopsy material rather than any actual increase in the incidence of periarteritis nodosa.

Of the total one hundred and forty-two cases only twenty-one have been reported in English, six from England, one from Australia, thirteen from the United States, and this one from Canada, most of the others occurring in Germany and Central Europe. Whether this greater incidence in that part of Europe is due to any racial or geographical factor, or whether it is due to an increased interest in the study of this peculiar arterial disorder it is impossible to say. The larger percentage of autopsies obtained in some of the continental clinics may influence the finding of this disease which, in nearly every case, is diagnosed only post mortem and frequently only after examination of the microscopical sections.

CASE REPORT

Mrs. B., housewife, aged forty-six years, was seen on March 29, 1928, complaining of recurring attacks of severe abdominal pain accompanied by nausea and vomiting, progressive loss of weight and strength, pain and weakness in left forearm and hand, and pruritus.

Present illness—In the late summer of 1926 patient had influenza and from that time had never been well. She had felt run down and complained of occasional asthmatic attacks. In July, 1927, the patient was advised to leave Ontario and come to Vancouver for her health. It was about this time that the

present symptoms were first noted, and they have persisted with gradually increasing severity. She had consulted numerous doctors without relief, the diagnosis being usually neurasthenia. Because of the persisting abdominal pain attention was directed chiefly to the gastro-intestinal tract and gall bladder, repeated x-ray examinations of which were negative.

In March, 1928, the patient consulted a gynecologist, Dr. J. J. Mason, who, in the course of his examination, had the blood examined. The count showed red blood cells 5,000,000, haemoglobin 80 per cent, white blood cells 32,000, polymorphonuclears 19 per cent, lymphocytes 10 per cent, monocytes 1 per cent, eosinophiles 70 per cent. The blood Wassermann was negative. Because of this unusual white cell count the patient was then referred to me for further study.

Past history—The patient was born in Ontario where she had always lived until coming to British Columbia. No significant previous illnesses. Tonsillectomy in 1926. Married three years, no pregnancies, catamenia regular.

Family history—Nothing relevant.

Physical examination (March 29, 1928)—The patient was acutely ill and showed obvious signs of loss of weight and strength. She was pale, with definite puffiness of the eyelids. There were numerous scratch marks on her skin and pruritus was a troublesome symptom. On the outer aspect of the lower third of her left leg was an irregular purpuric area several inches in diameter, undoubtedly aggravated by scratching. On both forearms, but more noticeable on the right, were a few small pea-sized non-tender subcutaneous nodules. Examination of her mouth, teeth and throat was negative. There were no enlarged lymph nodes. The thyroid was not enlarged. The pulse was 108, small and regular. The peripheral vessels, temporal, brachial and radial, all showed palpable sclerosis with beading and increased tortuosity. Blood pressure was systolic 160, diastolic 100. Temperature, 99°. The heart and lungs were normal. The abdomen was slightly distended, no rigidity, no free fluid. The liver was enlarged, extending from the fourth rib to three to four fingers' breadth below the costal margin in the mid-clavicular line, not tender. The spleen was not palpable and the area of splenic dullness not increased. Pelvis normal. Nervous system: the pupils reacted well to light and accommodation, no involvement of the cranial nerves, reflexes were normal, and there was no disturbance of sensation. There was slight weakness of the grip on the left side, with slight atrophy of the small muscles of that hand.

Diagnosis—The tentative diagnosis at this time was trichinosis or intestinal parasites. The diagnosis of parasitic infestation was based largely on the eosinophilia, and the subcutaneous nodules suggested trichinosis. The patient was sent to the Vancouver General Hospital for further examination.

First admission, (March 30, 1928, to April 14, 1928)—The temperature varied from 97° to 100.8°, and the pulse from 90 to 130, usually above 100. Respirations were normal. Patient complained of severe abdominal pains coming on in attacks at irregular intervals and associated with nausea and vomiting. These pains were so severe as to require morphine (grain ¼

* Presented at a meeting of the North Pacific Society of Internal Medicine, Vancouver, September 8, 1928.

hypodermically) for relief. Patient also complained of extreme general weakness, indefinite muscle pains, and pain and numbness in left hand and forearm. The abdominal symptoms had disappeared by April 6th, and the patient then began to feel better and was able to be up about the ward April 10th and to go home on the 14th. The purpuric area on the left leg had disappeared. Examination of eye grounds showed slight blurring of both discs and some peripapillary edema. The arteries were definitely sclerotic, showing irregularity of the lumen, increased tortuosity, and increased refractility. The veins appeared normal. There were no hemorrhages and no exudate. On April 5th one of the small subcutaneous nodules was excised from the dorsal side of the right forearm near the elbow, and was found to consist of a grayish white homogeneous mass 2 mm in diameter. It was examined microscopically for trichina but there was no evidence of this parasite. The nodule was found to consist of a fibrosis surrounding a

moderately large vessel, (Fig 1). No eosinophiles were noted in the surrounding infiltration. The right forearm was x-rayed because one nodule was attached to the ulna, but the result was negative. X-ray examination of the chest showed the heart and lungs to be normal, though the right diaphragm was elevated (enlarged liver). Repeated examinations of the stools for parasites were negative. For the blood count see Table I. Urinalysis was normal.

Second admission, (April 24 to 26, 1928)—Temperature, 98° to 98.6°, pulse, 90 to 120, respirations, 20. The patient re-entered hospital for further study. Her symptoms were increasing weakness, recurring abdominal distress, and increasing pain and weakness of both hands, more especially the left. The physical examination was similar to that on March 29th. The examination of the stools was again negative for parasites. For the blood count see Table I. While no definite diagnosis was attempted at this time, the following possibilities were considered: parasitic disease, in spite of negative stool examinations, and the absence of signs of trichina in the excised nodule; leukemia, because of the obviously progressive character of her illness, the extreme weakness and the unusual leucocyte count, and intra-abdominal disease because of the persisting abdominal symptoms.

Third admission, (May 15 to 26, 1928)—The patient was complaining of asthmatic attacks, debility, increasing weakness of both arms and hands, and recurring attacks of abdominal pain. Temperature was 97° to 105° (terminal pneumonia), pulse, 100 to 140, respirations, 20 to 30. The presence of an indefinite mass in the right abdomen (in addition to the enlarged liver), and the persistence of the abdominal pain, seemed to warrant further investigation. A barium enema showed a normal colon. Blood Wassermann again negative. Non-protein nitrogen, 36 mg. Urine, acid, specific gravity 1019, albumen a trace, sugar negative, red blood cells and hyaline casts present. For the blood count see Table I. The trace of albumen and red blood cells in the urine, the recurring abdominal pain, and the indefinite mass in the right upper quadrant suggested the possibility of right kidney involvement. Cystoscopy and pyelography on May 21st revealed normal

FIG 1—Subcutaneous nodule excised on April 5th. Note the marked fibrosis surrounding the small vessel in the centre of the nodule.

TABLE I

Date 1928	Red Blood Cells in Millions	Hemoglobin Per Cent	Colour Index	Staining	White Blood Cells	Polymorphonuclears	Lymphocytes	Monocytes	Eosinophiles	Number of cells Counted	Remarks
March 15	5.0	80	0.8	good	32,000	19	10	1	70	200	
March 31					31,200	11	9	1	79	200	Severe abdominal pain and vomiting

April 24					32,000	17	7		76	150	Recurrence of abdominal pain and vomiting
May 16	4.5	90	1.0	Irreg	21,000	58	5	3	34	100	Increasing evidence of peripheral neuritis. Progressive weakness
May 23					16,000	71	19	3	7	200	Acute pleurisy and pneumonia at the right base

kidneys and ureters, though the bladder was trabeculated. On May 24th the patient took a sudden chill and complained of severe pain in right lower chest. On May 25th there was evidence of right sided pneumonia and pleurisy at the right base. Death occurred on May 26th from pneumonia.

AUTOPSY

The autopsy was performed by Dr H H Pitts, pathologist to the Vancouver General Hospital, nine and one half hours post mortem, and his report follows.

The body was that of a fairly well developed, poorly nourished, white female, forty six years of age. Relatively little of note was apparent on external examination. The small subcutaneous nodules noted during life were still palpable on both forearms.

The right pleural cavity was partly filled with sero-fibrinous exudate which also covered the lung. The lung was compressed and practically the entire middle lobe was involved in a pneumonic process. The lung weighed 740 gm. The left lung was free in the pleural cavity, weighed 500 gm and on section showed scattered bronchopneumonic areas. The pericardial sac was intact. The heart weighed 270 gm. The valves, coronaries, and aorta were all intact. No gross evidence of arteriosclerosis and no beading of the coronaries. The musculature was pale and rather friable. Mediastinal glands were hyperplastic and congested.

The examination of the abdominal cavity revealed a liver of about normal size, but of a rather flattened, elongated type, a definite Reidel's lobe projecting downwards almost to caecum. The liver weighed 1,390 gm and on section presented a typical nutmeg appearance. No gross fibrosis was present. The gall bladder was intact and not particularly enlarged. The stomach was moderately distended but it and the duodenum were intact. The jejunum was intact, but in the lower three feet of the ileum three rather elongated superficial ulcerations were found, with little loss of tissue but some necrosis of the mucosa, no induration and considerable surrounding congestion. They appeared to be in the Peyer's patches. The large intestine was intact. The spleen weighed 125 gm and showed little of note on section. The uterus, tubes, and ovaries were intact except for two filbert sized intramural fibroids in the first. The kidneys each weighed 165 gm. The capsules stripped fairly easily, except in one or two areas, leaving a peculiar mottled appearance, with grayish white to yellow surface, and depressions of a more normal tissue running between elevated, more grayish white, areas. On section, the cortex was seen to be of normal thickness, with the same rather mottled appearance presenting and with scattered small cortical abscesses. The pelvis seemed intact. The ureteral mucosa was slightly reddened and the bladder mucosa trabeculated and pale, except at the ureteral orifices where some congestion was apparent. The bone marrow removed from one femur showed a reddish yellow, fairly normal gross appearance.

In none of the vessels, namely the mesenteric, splenic or renal arteries, were there any evidences of aneurysmal dilatations nor of any particular gross thickening of the vessel walls.

Diagnosis right lobar pneumonia and acute fibrinous pleurisy, left broncho pneumonia, ulcerative enteritis (ileum), chronic degenerative nephritis, multiple abscesses of the kidneys, myocardial degeneration.

Microscopical findings Heart sections through the heart muscle showed the muscle fibres to be somewhat swollen, fairly closely packed, the cross and longitudinal striations rather poorly defined, nuclei only fairly distinct. Myocardial degeneration. The branches of the coronary artery showed considerable increase in the thickness of the walls, this increase being largely a fibrous replacement of the media and adventitia (Fig 2).

Sections through the right middle lobe and pneumonic areas in the left lung showed all the alveoli to be

FIG 2—Branch of a coronary artery showing the great increase in the thickness of the walls, this increase being due to a fibrous tissue replacement.

completely filled with a cellular fibrinous exudate rich in polymorphonuclears, the blood vessels throughout being completely engorged and the alveoli airless, lobar and bronchial pneumonia. (No larger arteries were included in these sections.)

A number of sections were taken through the kidneys some to include the small abscess-like formations. These were seen to show complete degeneration of the tubular structure in the involved areas, the lining epithelium being completely fashioned into an amorphous mass, the glomeruli being similarly involved, while vast numbers of inflammatory cells were seen infiltrated throughout. These areas were surrounded by a deep zone of congestion. The sections through the elevated whitish areas in the kidneys showed large collections of small round cells with areas of fibrosis apparently conforming to these demarcations. This small round cell infiltration extended from these areas in a more diffuse but less abundant fashion throughout the whole kidney substance. The glomeruli themselves did not appear much involved, while throughout there was quite extensive congestion, the lining epithelium of the convoluted tubules being desquamated in many areas and, where present, appearing to be of a much lower type than normal. The fairly large branches of renal artery which were present in the sections of the kidneys showed considerable increase in the thickness of the walls, this increase being largely a fibrous replacement of the media and adventitia (Fig 3). Chronic degenerative nephritis.

FIG 3—Branch of renal artery showing increased thickness of wall due to connective tissue formation.

Sections through the liver showed an advanced stage of passive venous congestion, the central veins being deeply congested and the liver cells immediately surrounding and for a considerable distance around showing definitely atrophic changes, the whole having a very marked mottled appearance.

Several sections were taken through the ulcerated areas in the ileum but these only showed necrosis of the mucosa and, to some extent, the submucosa. Relatively little inflammatory cell infiltration was present, but well defined congestion of the vessels throughout. There were a number of fairly large submucosal vessels embodied in these sections which showed a condition of end arteritis rather than periarteritis, it would seem as if there was almost complete occlusion of the lumen by organizing fibrous connective tissue structure.

Sections through the spleen showed a moderate degree of passive venous congestion, but otherwise little of note beyond hypoplasia of the Malpighian corpuscles. The mediastinal glands also showed a very marked congestion, but otherwise there was little of note.

A number of sections were taken through the bone marrow and stained by various methods, but in none of these was there anything of particular note, certainly no evidence of increased eosinophile formation and no particularly abnormal cells. Several vessels present in these sections showed, as seen in other structures, definite thickening of the media and adventitia.

In an effort to establish a diagnosis in this case these sections were examined more particularly as regards the vascular channels and it was found in all that the larger vessels showed definite thickening of their walls (especially in the adventitia), many of these being increased approximately three or four times their normal thickness. This process held good only in the larger vessels, for instance, the small vessels forming the centre of the Malpighian corpuscles in the spleen showed no evidence of this fibrosis. There was only slight evidence of inflammatory cell infiltration within this fibrous connective tissue formation or surrounding it. No eosinophiles were noted in the cellular exudate.

Sections were taken from the various organs and stained with a variety of stains, i.e., van Gieson's Mallory's aniline blue, Unna's elastic tissue stain, and the two former showed well defined connective tissue increase in the walls, this connective tissue formation being in both media and adventitia, but most marked in the latter. With the elastic tissue stain the elastic laminae were clearly defined and showed evidence of rupture, especially clear in those vessels with the greatest increase in connective tissue formation (Fig. 4).

This was apparently a case of periarteritis nodosa.

FIG. 4.—Smaller branch of renal artery stained with elastic tissue stain. This shows the elastic laminae. In this case the intima is definitely deficient in part.

The gross findings did not conform to those found in many other reported cases but the microscopic examination of the blood vessels seemed to point undoubtedly to a lesion of this type.

The splendid review of the subject of periarteritis nodosa published by Gruber in 1926² furnishes a summary of the authentic cases to that date. Twenty-four additional cases have been reported since that time. A tabulation of all cases of periarteritis nodosa to the present time follows—

Gruber's above mentioned review has made available in German a summary of the clinical and pathological findings. It may be of some value so to summarize the cases reported in English that further interest in this unusual disease may be stimulated on this continent. A brief resumé of each of these is therefore presented, together with a table of certain data of interest and value in the study of periarteritis nodosa.

SUMMARY OF CASES REPORTED IN ENGLISH

DICKSON¹⁶ Messenger boy, fourteen years old. Initial complaints, cerebral symptoms. Febrile illness, convulsions. Diagnosis, tuberculous or pneumococcal meningitis. Duration of illness, fifteen weeks.

LONGSCOFF¹⁷ Coloured stevedore, aged thirty-five. Initial complaints, cardiac and arthritic. Widal repeatedly negative. Duration, eight weeks. Sudden death.

COOKE¹⁸ Boy, aged nineteen. Initial complaints, pain in the calves of legs while standing or walking. Febrile illness. Duration, eleven weeks. Sudden death.

LEWIS¹⁹ Plumber, aged thirty-three. Initial complaint, numbness and soreness of the hands. Febrile illness with irregular muscular pains. Loss of reflexes. Duration, ten weeks.

BEATTIE AND DOUGLAS²⁰ Cutler, nineteen years old. Diagnosis at first influenza, later typhoid fever. Duration, eight weeks.

* This case appears to have been overlooked by Gruber, yet it seems to be an authentic example of periarteritis nodosa.

† This case has not been verified.

LAMB ²⁰ Mechanic, aged twenty six Initial complaints, asthma, and an itchy, painful swelling about right ankle Purpuric eruption all parts of the body except face Severe abdominal cramps, joint pains Diagnosis, purpura rheumatica Duration, eleven weeks Eosinophiles up to 51 per cent

LAMB ²⁰ Girl, aged ten Initial complaints, epigastric pain and vomiting, sore throat Diagnosis, at first appendicitis Appendectomy Later, acute tonsillitis, acute nephritis, acute arthritis Duration, nine weeks Sudden death

KLOTZ ²¹ Woman, music teacher, aged thirty three Initial complaints, abdominal pain, pain in muscles and joints, tenderness over gall bladder Diagnosis, at first cholecystitis, possibly empyema of gall bladder, later, *streptococcus viridans* infection Duration, four weeks Sudden death resulted from rupture of a periarteritic nodule in the right lobe of the liver

KLOTZ ²¹ Man, aged fifty three, mail carrier Initial complaints, general weakness and nocturia Tonositis, purpuric nodules on legs and chest Diagnosis of Wilson's disease (degeneration of the lenticular nucleus) Blood Wassermann ++++ Duration, eighteen months Death resulted from hemorrhage into the peritoneum

CAMERON AND LAIDLAW ²² Newspaper cyclist, aged twenty seven Initial complaints, severe abdominal pain, extreme weakness and loss of weight Thickening of peripheral arteries Periarteritic nodules Febrile illness Diagnosis, at first tuberculosis of vertebrae, later arteriosclerosis, later malignant gastric disease Duration five months ? lues

MANGES AND BAEHR ²³ Man, aged thirty nine Complaints, recurring abdominal pain Exploratory laparotomy Periarteritic nodules in the mesentery Microscopic examination of excised nodule revealed typical acute changes Died four months after operation as a result of nephritis, with a terminal broncho pneumonia. Duration, six months

HARRIS AND FRIEDRICHS ²⁴ Coloured labourer, aged thirty two Initial complaints, weakness and abdominal pain Later, pain in the region of right kidney "Surgical abdomen" Duration, five and a half weeks

CARLING AND HICKS ²⁵ Engineer, aged thirty Initial complaints, severe pain and tender swelling in right calf Provisional diagnosis, gummatous infiltration, possibly sarcoma Exploratory incision showed "scattered nodules of a fibrotic nature about the smaller arteries" Microscopic examination of nodule showed typical periarteritic changes Nodules also developed on both arms Blood Wassermann ++++ Patient given intravenous injections of "salvarsan substitute" with apparent cure Duration nine months.

OPHULS ²⁶ Persian, janitor, aged thirty eight Complaints, abdominal symptoms for which an appendectomy had been performed, asthma, ascites, hydrothorax "Findings and the course of the disease were so unusual that the clinicians refused to make a diagnosis" Duration, eight months Death from myocardial weakness

WORDLEY ²⁷ Boy, aged thirteen A case of cortical necrosis of the kidney Haematuria, "fits," suppression of urine The only visible macroscopic periarteritic nodules noted were in the coronary vessels The kidneys showed microscopic evidence of typical changes of periarteritis nodosa Duration, two months

CLELAND ³ Man, aged eighteen years Mechanic Initial complaints, headache, abdominal pain Febrile course with rapid emaciation Evidence of involvement of the central nervous system. Diagnosis, typhoid fever, military tuberculosis Duration, nine weeks

KEEGAN ²⁸ Woman, drug addict, aged twenty four, with persistent abdominal symptoms and pus cells in the urine Exploratory laparotomy revealed no disease of the abdominal viscera Right kidney was then explored and removed Cross section showed numerous white milky nodules, microscopic examination of which showed periarteritic changes Patient died two months after

the operation as a result of cardiac insufficiency and pericarditis Duration three months

GRAY ⁷ School boy, aged twelve Injury to left knee, resulting infection of left thigh Febrile illness, with negative blood cultures Local inflammation subsided at the end of a month, but patient's condition steadily deteriorated Died from hemorrhage from a periarteritic aneurysm of the cystic artery Duration, nine weeks

SINGER ⁹ Coloured man, aged twenty nine Hyper-tension Diagnosis, catarrhal jaundice and a diffuse syphilitic hepatitis, in addition to chronic nephritis Cholecystectomy Two and a half months later patient was re-admitted to hospital with evidence of myocardial insufficiency which resulted in his death Arteries of the excised gall bladder showed changes suggestive of periarteritis No autopsy was performed

SINGER ⁹ Man, aged fifty seven, with symptoms of decompensation Hypertension Diagnosis, chronic nephritis, with myocardial insufficiency Febrile illness abdominal pain, definite signs of polyneuritis Diagnosis, morbus incognitus Autopsy revealed striking changes in the arteries of the walls of the gall bladder, in addition to changes in the vessels of the heart and kidney, typical of periarteritis nodosa

GENERAL ANALYSIS

A statement of the prominent features of these twenty-one cases is presented in Table III The paucity of clinical notes in some of these cases is an unfortunate result of the impossibility of making a diagnosis before autopsy There are certain points in this table which should be emphasized The temperature is practically always elevated, in only one of the twenty-one cases was it reported as normal Leucocytosis nearly always occurs, in only one of the cases in which the white blood cells were counted were they found to be normal The differential count usually reveals an increase in the polymorphonuclears, though in three cases, including the present one, an eosinophilia occurred Urinalysis reveals the frequent occurrence of albumen in small amounts and the presence of hyaline and granular casts Abdominal pain was the most prominent clinical symptom, occurring in fifteen of the twenty-one cases The liver was frequently enlarged, whereas the spleen was only found to be increased in size in one instance Other symptoms were found less often Skin manifestations occurred in eleven cases, arthritis in six, peripheral neuritis in five sore throat in four and asthma in three

DISCUSSION

With the accumulation of these case reports there have grown up certain ideas regarding periarteritis nodosa which it may be well to discuss

Age—The disease may occur at any age, in

fact Gruber² records instances of periarteritis nodosa in a baby two and a half months old and in a man seventy-eight years old. Most cases occur, however, in the third and fourth decades, at the time of life when infections and infectious processes are most common.

Sex—The disease is more common in man. Gruber² states the sex in a series of one hundred and thirteen cases, eighty-seven of which were men and twenty-six women, and in this present tabulation of twenty-one cases, seventeen are men and four women. Periarteritis nodosa is therefore three to four times as common in men as in women.

ETIOLOGY

The cause of periarteritis nodosa is as yet unknown. Since the disease was first recognized various theories have been advanced, some of which deserve mention only to be excluded.

Syphilis—At one time syphilis was thought to be the cause of periarteritis nodosa as it has frequently been blamed for many another obscure disorder. The fact that there is a true syphilitic arteritis confused the issue for some time. However, in periarteritis nodosa the Wassermann reaction has usually been negative and histological examination of the arterial lesions stained by the Levaditi method has repeatedly failed to show any spirochaetes. It seems definitely established that syphilis plays no part in the production of the lesions of periarteritis nodosa. The fact that the disease has been found in animals, *i.e.*, the deer, calf, pig and dog² further excludes the possibility of syphilis as the cause.

Mechanical causes—The rather bizarre idea was at one time advanced that the multiple aneurysms found in cases of periarteritis nodosa were due to a rupture of the elastic membranes caused by increased intravascular pressure. Needless to say, careful study of the pathogenesis of the lesions of periarteritis nodosa readily disproved this idea.

Parasites—The theory that periarteritis nodosa might be due to parasitic disease gains strength from certain observations quoted by Cameron and Laidlaw²². There is a disease of horses characterized by multiple aneurysms along the mesenteric vessels which is known to be due to the parasite *Strongylus armatus* and certain aneurysms in dogs are caused by a

nematode worm *Spioecirca sanguinolenta*. In the latter the mode of attack of the vessel, the resulting degeneration of the media, and the formation of aneurysms, is most suggestive. The presence of an eosinophilia favours parasitic disease. This blood finding, however, is not universal and it hardly seems possible that the causative parasite could have been overlooked in all the cases studied.

Streptococci Septicæmia—A streptococcal septicæmia was at one time thought to be the cause. Numerous cultural studies that have been made, however, both on the blood and other body fluids before death, and on the blood and various tissues after death, refute the possibility of an acute streptococcal infection as the cause of periarteritis nodosa.

There remain three possibilities to be discussed in connection with the present view as to the etiology. These are (1) the filterable virus, (2) rheumatic infection, and (3) the idea that periarteritis nodosa is not due to any specific cause but is rather a reaction on the part of the vascular tissues to certain "toxic" or "infectious" factors.

Filterable Virus—Harris and Friedrichs²³ were able to produce in a rabbit typical changes of periarteritis nodosa from intravenous injection of a filtrate prepared from the organs of another rabbit that was killed two and a half months after inoculation with a suspension made from the nodules of a human case. In their opinion periarteritis nodosa is due to a specific causal agent, a filter passer. These results have not yet received verification from other studies. In fact, Otani²⁴ has challenged them, and Franz⁶ failed to reproduce the disease in guinea pigs. Even so, a filterable virus must still be considered as one of the possible causes.

Rheumatic Infection—While an acute streptococcal infection is not a likely cause of periarteritis nodosa, the less virulent type of streptococcus associated with rheumatic fever may be the offending organism^{21, 25}. The not unusual association with sore throat, the arthritis and muscle pains, some of the cutaneous manifestations, and the leucocyte count, all suggest an infection, and an infection of the rheumatic type. The pathogenesis of the lesions in periarteritis nodosa also is extremely suggestive of an infectious origin. The early cases show acute inflammatory changes, which later,

if time permits, develop a sclerosis as an attempt to heal the injury wrought by the acute manifestations. This process is well illustrated by the case of Manges and Baehr,²³ in which a periarteritic node removed at operation showed definite acute and subacute reactions, while the study of the autopsy material, obtained three and a half months later, showed none of these acute changes.

The third remaining view as to the etiology of periarteritis nodosa is that it is not a disease *suu generis*, but rather a reaction on the part of the organism to some unknown factor, the reaction being located in certain areas of the arterial system. This theory, while not at all new, is strengthened considerably by the fact that it has received the support of Gruber who has given the subject considerable attention. The changes in the arteries may be a non-specific response to a number of different agents, toxic or infectious as the case may be, or these reactions may be evidences of a hypersensitivity to some bacterial organism. The latter possibility is of interest in connection with the relation to rheumatic infection. As already pointed out there are certain points of resemblance between periarteritis nodosa and rheumatic fever, and further consideration should be given this possible relationship. A recent suggestion, by Swift and his co-workers,³¹ regarding the possibility that rheumatic fever itself is a hypersensitivity to a non-haemolytic streptococcus is of considerable interest. The present stage of our knowledge of periarteritis nodosa does not permit of conclusive views as to either the cause of the disease or the pathogenesis of the lesions. The possibility that periarteritis nodosa also may be a hypersensitivity is worth considerable thought. This hypersensitivity may be to a filterable virus or to a non-haemolytic streptococcus, or to any other as yet unknown organism.

PATHOLOGY

The pathology of periarteritis nodosa is not entirely established, for while it has received much more consideration than the clinical condition, there are still divergent views as to the pathogenesis of the described lesions. No attempt can be made in this paper to enter into any discussion of the pathology of periarteritis nodosa and the following views are in the nature

of a summary of what appear to be the most logical of the recent opinions.

Periarteritis nodosa presents an involvement of arteries of the size of the coronary and main branches of the renal artery, the larger vessels, the aorta and its main branches, usually escape and these smaller vessels bear the brunt of the attack. The most frequent location is in the principal divisions of the renal arteries.² The next most frequently involved are the coronary vessels, then in order the mesenteric vessels, the branches of the hepatic artery and cystic arteries, the arteries to the other viscera, the cranial arteries, and the peripheral arteries. The predominant involvement is, therefore, in the medium-sized arteries. Extension is seen into the branches of these arteries and may even extend to arteries of very small calibre. Venous involvement has been described^{2, 26} but is not usual.

The pathological changes may be divided into (1) the changes found in the vessels themselves, and (2) the changes occurring in the organs and tissues as a result of the disturbed circulation.

GROSS CHANGES

The involved arteries may show small aneurysms or nodular formation, or may only reveal a diffuse thickening without any nodular appearance. Nodosities, when they occur, may be very profuse, even to the extent of producing a resemblance to a string of beads. These nodules may, on the other hand, be widely scattered and only discovered after careful search. The cases of periarteritis nodosa in which no nodule formation can be seen and in which involvement is entirely diffuse are those in which a diagnosis can only be made after careful examination of the microscopic sections. Lamb²⁰ mentions this occurrence in five cases and points out that this fact may lead to the disease being overlooked both clinically and pathologically. That such is not often the case, however, is shown by the further fact mentioned by Lamb that in a review of all cases of nephritis occurring at the Presbyterian Hospital during a period of six years no case of periarteritis nodosa was found, although a careful search for the disease was made. The arterial involvement may be localized to any one organ, or any one part of the body, or it may be diffuse. Extravasation of blood from rupture of one of these small aneurysms or diseased vessels

may occur producing, for example, hæmorrhage into the peritoneal cavity, gall bladder, perirenal spaces, cranial cavity, and so forth.

The gross appearance of the heart is often strikingly characteristic. On opening the pericardium the coronary vessels stand out as thickened nodular cords. The kidney may present gross evidences of the disease, showing miliar nodules scattered throughout the substance, particularly visible on longitudinal section. Involvement of the intestinal tract may occur as a result of thrombosis of the mesenteric vessels, infarction or ulceration, particularly in the ileum. The liver in most cases is enlarged and on section presents fibrosis or passive congestion.

MICROSCOPICAL CHANGES

The microscopical appearance of an affected vessel depends upon the stage of the disease. Early there is an acute perivascular infiltration extending into the adventitia. This cellular infiltration is usually polymorphonuclear, though it may be round-celled or occasionally may consist of eosinophiles.^{1 26} The congestion resulting from this infiltration leads to an occlusion of the vasa vasorum, with a resulting necrosis of the media and a weakening of the elastic laminae. Necrosis in the media is followed by a hyaline connective-tissue replacement, which also occurs in the adventitia. The weakening of the elastic laminae results in rupture which frequently leads to the aneurysm formation so typical of the disease. At times the involvement of the vessel is focal, so that nodular formation may occur as a result of the increased thickening of the layers of the arterial wall but without true aneurysm formation. The intima is not usually involved though even this coat may not escape. Thrombosis is a frequent result, especially when aneurysm formation occurs, and may go on to complete occlusion of the vessel, producing an infarct, or at times evidence of recanalization can be found. The late stages of periaortitis nodosa present a striking fibrous tissue thickening of the arterial wall, particularly the media and adventitia, this fibrous tissue occurring in an irregular arrangement that produces a diffuse or nodular involvement of the artery. In these late stages the cellular infiltration has usually disappeared. The

spread of this inflammatory process is by way of the perivascular lymphatics.²¹

The microscopical changes produced in the viscera are those depending upon interference with the blood supply and are cloudy swelling, fatty degeneration, cortical necrosis or other evidences of cellular destruction. This results in the nephritis, myocardial degeneration, ulcerative enteritis, cerebral involvement, and so forth, that may develop in these cases and which may so dominate the picture, both clinically and pathologically, as to obscure the true diagnosis. The kidneys show the most marked changes, early involvement causing tubular degeneration often to the extent of fibrous tissue replacement. This process may go on without involvement of the glomeruli, though at times there is an extension of the inflammatory process into the kidney substance with widespread destruction of renal tissue. Involvement of the arteries of the heart leads to the usual picture of cardiac muscle degeneration. The liver is frequently the site of an extreme grade of passive congestion which may present the appearance of evanescent atrophy. The reason for this congestion is not entirely clear, since it is out of proportion to other evidences of myocardial weakness. At times there is a considerable fibrosis present in the liver substance. Infarcts may occur in any of these organs or in other involved areas.

Periaortitis nodosa is a vascular disease and it is only the arterial lesions that are typical. A fatal outcome in periaortitis nodosa may occur as a result of injury to the vessel itself as rupture or thrombosis or as a result of degeneration of an organ as a consequence of this arterial disease.

SYMPTOMS AND PHYSICAL SIGNS

As might be expected from the complex character of the pathological findings, the symptoms of periaortitis nodosa are many and varied. The onset of the disease may be acute or insidious, the acute onset being associated with the more fulminant type of case, whereas the insidious onset usually occurs in the chronic case. Abdominal pain is a very frequent symptom. The origin of this pain is not entirely clear, most writers being satisfied with the explanation that it is due to involvement of the mesenteric vessels. Weakness is another symptom prominent out of all proportion to

the severity of the physical signs of the disease. This weakness is such an outstanding feature that chlorotic marasmus is frequently mentioned, particularly in the earlier descriptions of periarteritis nodosa. Loss of weight is usually a noticeable feature, in the more acute forms of the disease this weight loss being the rapid emaciation of an acute illness, while in the chronic forms there is usually considerable gradual loss of weight accompanying the loss of strength. Most of the cases of periarteritis nodosa exhibit a temperature at some time in their course, though fever is not a constant symptom. In some instances the febrile course is distinctly septic, while in others the temperature is subfebrile.

The pulse is rapid, usually out of proportion to the degree of temperature, and this tachycardia has received much comment. The frequency of involvement of the coronary vessels would naturally lead one to anticipate a certain amount of myocardial insufficiency, which would account for this increased pulse rate. Dyspnoea also may be noted, although it is by no means the pronounced distress which characterizes a failing myocardium. Other evidences of decompensation, as œdema and cyanosis, are not common, though œdema may occur as a result of renal insufficiency.

Blood pressure in those cases in which it is recorded is frequently elevated. The urine usually shows a small amount of albumen, and very frequently hyaline and granular casts. These evidences of renal involvement are not surprising in view of the frequency with which the disease attacks the renal arteries.

In a number of cases sore throat has been noted at the onset of the disease. Pains in the muscles are a common feature. These pains may be so severe as at times to suggest an actual invasion of the muscle tissue, so that polymyositis is a common finding in the clinical picture. Arthritis has also been noted. In fact the occurrence of these three symptoms has given additional weight to the theory that periarteritis nodosa may be a manifestation of a rheumatic type of infection. The patients in some of the reported cases have suffered from asthma and the possibility of periarteritic involvement of the bronchial vessels makes this symptom a likely one in any case.

Peripheral neuritis occurs fairly frequently

Whether this neuritis is a result of decreased blood supply to the peripheral nerves because of periarteritic involvement of their nutrient vessels, or whether the neuritis is a toxic result of the disease itself is not entirely clear.

Various skin manifestations have been reported in this disease. In addition to the subcutaneous nodules which occur as a result of the involvement of the arteries in this area other skin lesions may present themselves. Urticaria and pruritus are commonly noted. Purpura occurs at times during the course of the disease, at other times it is a terminal feature.

The liver is usually enlarged, though the reason for this is not altogether clear. The moderate evidence of myocardial insufficiency would account for a certain degree of passive congestion which is frequently found in the liver, but would not explain the extreme degree of congestion which is out of all proportion to the other evidences of congestive heart failure. The spleen is seldom enlarged.

Leucocytosis is invariably present. This leucocytosis varies from 10,000 to 30,000 per cmm., or in some few cases even to 40,000 or higher. The differential count usually shows a preponderance of polymorphonuclears with, in some few cases, increased eosinophile counts. There is usually, though not invariably, an accompanying secondary anaemia.

When the cerebral arteries are involved symptoms due to the involvement of the central nervous system are prominent. Cranial nerve lesions may occur, and delirium, convulsions and varying degrees of coma may be noted.

Death may occur suddenly from rupture of an aneurysm producing a fatal hæmorrhage, or may be due to secondary degeneration of certain organs as a result of the arterial disease producing, for example, uræmia or myocardial failure.

DIAGNOSIS

The disease is a sub-acute, febrile, wasting illness, characterized particularly by abdominal pain, unusual leucocytosis, peripheral neuritis and myositis and evidence of nephritis. When subcutaneous periarteritic nodules occur (in 20 per cent of cases) the possibility of making a diagnosis is increased. The course of the disease is characterized by irregular exacerbations and remissions. The varied nature of the symptom

complex has naturally led to an extremely wide range of ante-mortem diagnoses, those most commonly noted are sepsis, typhoid fever "acute abdomen", trichinosis, nephritis, peripheral neuritis myositis, miliary tuberculosis, dysentery, purpura, meningitis, encephalitis, or any one or a wide variety of other conditions. The cardinal symptoms of periarteritis nodosa are gastrointestinal manifestations, chlorotic marasmus, peripheral neuritis and nephritis.

DURATION

The duration of periarteritis nodosa shows considerable variation from case to case, although the duration period reported must be accepted with reservations because of the frequent insidious onset and also because of the fact that clinical observation in these cases has often been most fragmentary, the diagnosis only being made after death. The duration reported varies from six days to two years. The average duration in fifty-eight of the cases reported by Gruber,² in which sufficient information is given to be accurate regarding this point, was 47 months.

PROGNOSIS

The prognosis in a disease almost always diagnosed after autopsy is apt to be very bad. Gruber in fifty-four cases, reviewed in his 1926 article, mentions four cures, two of which he queries, while in my twenty-one collected cases there was only one cure. It is generally believed that some mild cases may go on to recovery. The pathological evidence seems to show that there is a definite effort at repair and it is possible that the mortality in this condition may not be so high as the above mentioned figures would indicate. The fact that the changes of periarteritis nodosa are very rarely found at post-mortem examination, even where large numbers of autopsies are done, would indicate that it is a rare disease with a high mortality.

TREATMENT

Since the cause of the condition is unknown the treatment is entirely symptomatic. It is of interest to note that in the case reported by Carling and Hicks,²⁵ recovery occurred after the administration of an anti-syphilitic arsenical given intravenously. The exhibition of such a drug would seem to be indicated in cases where the diagnosis is established at a time when treatment might be of some value.

DISCUSSION OF SPECIAL FEATURES IN THIS CASE

The case here reported presents certain features which merit further consideration.

Absence of Anæmia — The absence of anæmia in this case was one of the factors which prevented a proper diagnosis being made before death. A cursory review of available text-book descriptions of the disease, at the time the subcutaneous nodule was excised, stressed secondary anæmia as a most prominent feature of the condition. In this case the red blood count was five millions at first and even shortly before death had only fallen to four million five hundred thousand. In spite of this high red count the patient presented a marked pallor, which point, with her weakness, might easily have been interpreted as the chlorotic marasmus of the earlier descriptions.

Unusual Eosinophilia — The unusual differential count presented in this case a very striking feature. The eosinophiles at one time reached 79 per cent of 31,000 white blood cells. It was the presence of this eosinophilia which at first made us consider a diagnosis of parasitic disease. The combination of the eosinophilia and subcutaneous nodules, with pain in the muscles, led us to a tentative diagnosis of trichinosis. In this connection it is of some interest to note that Kussmaul and Maier in their original report thought at first they were dealing with an unusual case of trichinosis because of the subcutaneous nodules and muscle pains, and only after autopsy did they discover the unusual character of the arterial lesions. Eosinophilia has been reported in a few cases,^{18, 20} although in none has it been so high as 79 per cent. This case did not show the presence of eosinophiles in the cellular infiltration in the periarteritic lesions. This is of interest in connection with the case reported by Ophuls,²⁶ in which eosinophiles were present in the cellular exudate but were not increased in the circulating blood.

Asthmatic Attacks — The asthmatic attacks occurred early in the disease, and even after disappearing recurred again shortly before death. The microscopic sections of the lungs in this case did not show evidence of periarteritic disease. It is possible that more careful examination including the branches of the pulmonary artery and the bronchial vessels might have revealed such evidence. The fact that a diagnosis

of periarteritis nodosa was not made at the time of autopsy prevented us from collecting as complete a series of tissue sections as otherwise might have been done.

Peripheral Neuritis—Peripheral neuritis was noted in this patient on my first examination. At that time there was a slight but definite atrophy of the smaller muscles of the hand and complaint of persisting neuritic pain in the forearm and hand. This neuritis progressed in the course of the illness until shortly before death it was a much pronounced feature.

Abdominal Pain—The abdominal symptoms shown were striking, the patient having recurring paroxysms of abdominal pain associated with nausea and vomiting. The pain was umbilical or epigastric in location and came on in attacks which persisted for varying periods. The pain was not accompanied by any evidence of peritoneal irritation, and there was no rigidity of the abdominal wall. The pain was not associated with the taking of food and was definitely remittent and during these remissions the patient was free from gastro-intestinal disturbances.

Skin Manifestations—Pruritus was an early feature which was largely disregarded because of the neurotic nature of the patient. This itching was at times accompanied by an urticarial eruption. At other times the pruritus was severe without any visible evidence of skin lesion. Purpuric spots were not frequent, the one purpuric area that was found was a large patch on the left leg which was undoubtedly factitious in origin.

Renal Insufficiency—The clinical evidences of renal insufficiency were slight as compared with the pathological evidence of kidney involvement. This is in part undoubtedly due to the fact that the kidney lesion was a tubular one resulting from the arterial disease. It is possible that had the patient escaped her terminal infection further evidence of nephritis would have appeared. Death was due in this case to an intercurrent infection, a terminal pneumonia with an acute pleurisy. It is interesting to note that the white blood cells which had been persistently high fell after the onset of the pneumonia. With this fall in the white blood cells there was an increase in the polymorphonuclears.

Duration—In this patient the symptoms of her last illness could be definitely traced back eleven months before her death. This is longer

than the average duration (4.7 months). The pathological changes observed in the vessels in this case would suggest a long course, the acute cellular reaction having subsided and hyaline-tissue replacement being well advanced.

Pathology—Except for the subcutaneous nodules, one of which was removed before death, and the character of which we failed to appreciate, there was no other gross evidence of nodosities of the arterial walls. This is not entirely unusual. Lamb has noted the fact that in five cases no gross evidence of the disease was apparent and the only evidence was microscopic.²⁰ There was an unusual degree of passive congestion of the liver in this case. This passive congestion was out of all proportion to the other signs of heart failure and was apparently a result of a disturbed circulation to that organ. The kidneys presented a most unusual appearance, grossly they showed areas of pallor, alternating with areas of congestion. There were, in addition, a few small cortical abscesses, possibly infected infarcts. Microscopically, the lesion was a degeneration of the tubules with very marked periarteritic involvement of the renal arteries. Involvement of the veins, reported in a few cases,^{2, 26} was not noted. The finding of several ulcerated areas in the ileum, which could be accounted for at the time of autopsy, is readily understood by the periarteritic involvement of the arteries in the intestinal wall shown in the sections. The ulcers were obviously early and could have produced no serious clinical effects.

SUMMARY AND GENERAL CONCLUSIONS

1 A case of periarteritis nodosa in a woman of middle age. The disease was of long duration, subfebrile, and characterized by intermittent abdominal pain, progressive weakness and peripheral neuritis of the upper extremities. Subcutaneous periarteritic nodules occurred, one of which was excised. The diagnosis was not made at that time, but was only established after study of the microscopic sections taken at autopsy. There were no other gross evidences of nodular arterial disease.

2 The eosinophilia, up to 79 per cent, is unusual.

3 This case throws no definite light on the etiology of periarteritis nodosa. The most likely possibility seems to be a rheumatic in-

fection, with the changes either the result of the invasion of the causative organism (streptococcus ?) or the result of a hyperergy to such an organism, in this disease this hyperergy being manifest in certain areas of the arterial system.

THE DIAGNOSIS AND TREATMENT OF PERNICIOUS ANÆMIA*

BY EDWARD S MILLS, M D

Montreal

THE existence of a formative and healing power inherent in the organism, by which it preserves itself and combats morbid causes and their effects, is one of the great discoveries of Hippocrates. Even in the present era of medicine we are but beginning to understand the nature and location of some of these forces, to recognize their deficiency, and to devise methods of substitution when they are inadequate. Kendall made possible scientific thyroxin therapy, Banting followed with insulin for diabetes mel-

litus, and Minot and Cohen have just shown that pernicious anæmia may be controlled by the oral administration of an aqueous extract of liver.

Someone has aptly remarked that the first step in treatment is diagnosis, that the second is diagnosis, and that the third is diagnosis. This aphorism seems to be particularly applicable to pernicious anæmia. In its diagnosis due consideration must be given to every fact which can be elicited as a result of both clinical and laboratory study. There is no single characteristic of the disease which may not be present in other entirely independent pathological states. Par-

*Read before the Ontario Medical Association, Kingston, May 31, 1928

æsthesia, asthenia, and progressive pallor with good nutrition, a lemon tint of the skin, atrophy of the tongue, and achlorhydria occurring in a middle aged person are at once suggestive of the disease but are not diagnostic. It is not many months ago since a case, in our experience, presented the above signs and symptoms, and these were considered sufficiently complete to disregard a blood report entirely unfavourable to the diagnosis of pernicious anæmia. Some months later the man reported with an inoperable carcinoma of the stomach. In another instance, to the chagrin of the hæmatologist, a case presenting typical blood features proved later to be a slowly progressing aleukemic lymphosis. It is only by the careful weighing of all available evidence that such mistakes can be avoided.

The time of onset of pernicious anæmia is commonly from the fifth to the seventh decades. The youngest case admitted to the Montreal General Hospital in five years was 31, and the oldest 72. The tint of the skin is often striking, varying from a pale waxy sub-icteroid tint to a definite ochre colour, or actual bronzing if the patient has had prolonged arsenic therapy. The nutrition is said to be maintained, but in our experience it is not uncommon to find a considerable loss of weight. Seventy-five per cent of our cases weighed 125 lbs or less on admission. The atrophy of the tongue begins at the tip and edges and may involve the entire dorsum. Small ulcers are not infrequent. Achlorhydria is universally considered as a *sine qua non*. The blood pressure is seldom if ever elevated. It is usually below the expectancy for the age, the highest systolic pressure recorded in our series was 150 mm Hg.

Degenerative changes in the central nervous system, as a rule involving the posterior and lateral columns of the spinal cord, are invariably found if they are looked for. During the years 1925, 1926 and 1927, out of 56 recorded cases, 48 showed undoubted evidence of this degenerative process. Prior to this time the incidence was found to be much lower, because it was not often recorded. The most common symptom to which this form of sclerosis gives rise is paræsthesia in the extremities, with numbness, tingling, or a sensation of "pins and needles". On examination, it is rare to find any alteration in tactile, painful, or thermal sensation, but the vibratory sense and two-point discrimination are almost constantly affected. Paresis of the legs is not uncommonly present, but it rarely proceeds to definite paralysis. The myotatic reflexes are

frequently absent, but they may be exaggerated and associated with marked ataxia and clonus. The involvement of the motor tracts is indicated by the Babinski phenomenon. The innervation of the bladder is rarely attacked—only twice in the series. An acute psychosis occurred five times. The following statement shows the frequency of the various signs referable to lesions in the nervous system.

Number of Cases (1925, 1926, 1927), 56, paræsthesia, 48, vibratory sense or two-point discrimination, 31, atonia, with diminished or absent reflexes, 9, ataxia, with exaggerated reflexes, 5, Babinski phenomenon, 8, acute psychosis, 5. Occasionally cases of pernicious anæmia make their appearance with signs and symptoms directly referable to the central nervous system. The main complaint is difficulty in walking, weakness in the legs, or paræsthesia. Clinically, there is little or no evidence of anæmia. On examination of the blood, however, the characteristic picture is present, though the actual reduction in the cytological elements may not be great. These cases are often most discouraging from a therapeutic standpoint, for, though the blood may improve, the cord changes are often progressive, eventually involving the brain itself, with a fatal outcome. In two of three such cases in our series treatment failed to influence the progress of the process, while in the third it was apparently successful.

The blood picture has long been considered to indicate a hyperactive process of destruction and regeneration. The anæmia, with excess of bilirubin seems to point to rapid hæmolysis. The abundance of immature cells, notably reticulocytes, macrocytes and megalocytes, indicates hurried formation. On the other hand, the late Professor Peabody's investigation rather suggests that this blood picture may be due to a functionally inefficient marrow with lack of utilization of blood pigment. Be this as it may, a high colour index, bilirubinæmia, macrocytosis, increase in reticulocytes, leucopenia with relative lymphocytosis, are features of the disease. In this connection it may be stated, that a smear of blood showing a predominance of large highly coloured erythrocytes is much more characteristic of pernicious anæmia than is a smear showing a number of small and deformed cells of various sizes and shapes, whether these be nucleated or not (see Fig 1).

Each case of possible pernicious anæmia should, therefore, be investigated and judged on the basis

FIG 1—Microphotograph of a smear of blood obtained from the case represented in Chart III. For comparison with it, is a smear of normal blood photographed at the same time using the same magnification. The pathological cells (on the right) are larger, more deeply coloured, and more variable in size.

of the following: (1) Atrophy of the tongue and achlorhydria, (2) Pallor of the icteric type, (3) Signs of subacute sclerosis of the nervous system, (4) Reduction in the number, but increase in the size of the erythrocytes, high colour index, leucopenia with relative lymphocytosis, and increase in the plasma bilirubin, (5) Excess of urobilinogen in the urine. The absence of one or more of these features is insufficient to exclude the disease.

For the present effective treatment of pernicious anaemia let us pay ungrudging tribute to the fundamental observations of George Whipple, of Rochester. To him and to his co-workers should go the credit for the experimental demonstration that liver occupies the supreme position as a regenerator of blood. The successful clinical application of his experimental results, as applied to pernicious anaemia, was first demonstrated by Campbell P. Howard, now of McGill. The more recent and more detailed studies of George Minot and the Boston group of investigators have placed the liver treatment of this disease upon a sound practical basis, and have convinced practically the entire medical world of its clinical value, in an incredibly short period of time. From England, from Australia, and from the Continent, corroboration is forthcoming. Finally Cohen, in conjunction with Minot, was able to recover from liver an aqueous extract many times more potent than the original substance in the treatment of pernicious anaemia. The nature of this effective liver fraction and its

mode of action are both uncertain at the present time. In the process of its separation from liver, proteins and iron are removed by fractional alcoholic precipitation. The final water-soluble moiety contains the active principle. Speculation is rife as to its nature. It is claimed to be a vitamin, but the word "vitamin" is being used too loosely nowadays to convey any accurate meaning. It is known that the fraction contains a substance or substances in the polypeptid or amino-acid groups, for it gives the biuret reaction. All else is theory.

Little more is known of its mode of action. From Peabody's recent investigation of the bone marrow before and during liver treatment, it would seem that the active fraction enables the erythroblastic process to proceed to maturity. After liver therapy, though the marrow may have a less active appearance, functionally it is much more efficient, it can produce more red cells per unit of time. Whether this is accomplished by the neutralization of the effect of some unknown bacterium, or by the addition of a hormone deficient in the disease, or by some other means, is a problem yet to be solved.

The question of whether liver is effective in anaemias other than the Addisonian type is so frequently asked that a brief digression here may be pardoned. We have tried liver therapy in a considerable number of cases of the secondary type of anaemia, in which the etiology was obscure, with excellent results. One should recall that the entire experimental investigation which proved its worth was carried out on dogs with a secondary form of anaemia. The explanation would seem to be that whole liver supplies an abundance of iron in a readily assimilable form.

So much for the scientific side of liver therapy. We now turn to the more practical question of how to obtain results with it. The patient should be put to bed, as rest is an important factor, especially if the anaemia is severe. The diet should be well balanced, relatively low in fat, and should include raw or cooked liver in amounts from 200 to 500 grams a day. It is usually advisable to give dilute HCl with the meals. When the blood values have been restored to normal, which usually requires from six to eight weeks, its continued use is still a necessity. The daily amount may be reduced, and in certain cases three liver days a week seem to be adequate. The necessary amount in each individual case must, of course, be gauged by the results. A monthly check of the blood will tell whether

sufficient is being taken. What is adequate in one case may be inadequate in another.

The liver may be prepared to suit the palate of the patient. It may be ground up in soup, served as a cocktail, made into sandwiches, or even added to chocolate ice cream. It should not be boiled, however, as the potent portion is soluble in water.

Where the anæmia is grave and attended by nausea, vomiting, and intolerance to food, liver extract is indicated. We have tried the effect of four different samples, manufactured by three different pharmaceutical houses. The method of assay which was adopted was as follows. The patient was put to bed, and placed on an ordinary hospital diet, plus the extract to be tried in daily amounts equivalent to 400 to 500 grams of liver. The reticulocytes were counted daily. If at the end of a ten-day period there was no appreciable rise in the percentage of these young cells in the circulating blood, the sample was discarded as non-potent. An instance of the failure of one sample, and the prompt response to a second, is shown in Chart IV. Both the Lilly Fraction and the Connaught Laboratories Extract were found to be of satisfactory potency.

The effect of liver and liver-fraction therapy on the cord changes is less striking than on the blood. In most cases, probably the great majority, the progress is apparently arrested, provided the blood is maintained at a normal level. Occasionally, marked improvement occurs, especially in the tabetic type which seems to respond better than do the spastic cases. One of our cases, who took only sufficient liver to maintain the blood at the three million level, showed, after a time, progressive cord lesions of the spastic type. When he was given liver fraction the blood showed a rapid rise to the normal figure. With the aid of physical therapy the clonus and Babinski sign disappeared, and he is slowly regaining his normal gait. In a few cases, and this is specially true of those in which cord signs and symptoms predominate from the onset, little or no beneficial effect other than on the blood is noted, and the case progresses to a fatal termination though the blood count may improve considerably. Fortunately, this latter type is rare, there were only two in this series. Taking the disease as a whole, it is evident that early diagnosis and prompt adequate treatment are essential if permanent cord damage is to be prevented.

In the accompanying tables the effect of liver

and of liver fraction therapy are graphically represented. It will be noted that the first sign

CHART I—This shows the effect of whole liver (300 gm. per day) on the hæmoglobin, the red cells, and the leucocytes in a case of pernicious anæmia. The time period was 40 days, the same as in Charts II, III, and IV.

CHART II—This shows the effect of liver fraction (Lilly) (equivalent of 300 gm. of liver daily) on the hæmoglobin, the red cells, and the reticulocytes, in another case. The arrow indicates the point at which treatment was begun. It is to be noted that the reticulocyte level rises before improvement is noted in the red cell count.

CHART III—This shows the response of another case to a different type of extract (Connaught Lab extract, equivalent of 450 gm. of liver daily).

CHART IV—This shows the failure of a non potent extract of liver, and the prompt response to another type, used on the same case. The arrows indicate the points at which each was begun

of improvement in the blood picture is a rise in the reticulated red cells, indicating an improvement in the numerical output of cells from the bone marrow. This is noted for several days prior to a demonstrable rise in the actual number of red cells per unit volume of blood. During this time there is a considerable improvement in the patient's subjective symptoms. The tinnitus, or pounding in the head, disappears, the lethargy is replaced by alertness, and the anorexia by a desire for food. In a few days the rise in the blood count is noted. It progresses at an almost surprising rate until the three million level is reached, after which the rise is much more gradual. Perhaps the most interesting case, from a therapeutic standpoint, which has come under our observation, is one which has been watched continuously since 1919. (See Chart V.) During 1920 and 1921 the effect of transfusions was observed. In 1921 splenectomy was performed. In 1924-1925 transfusion was combined with iron and arsenic therapy. Finally 300 grams of liver daily was substituted. The improvement was rapid and so far permanent.

Varicose Veins—H. O. McPheeters and Carl O. Rice, Minneapolis, believe that the treatment of varicose veins by the injection method should not be attempted by those who are not aware of the complications, as an unduly zealous individual may bring into disrepute through errors in technique a very satisfactory mode of treatment. The mortality rate following the injection treatment of varicose veins is much less than with the operative treatment. There is not, as yet, one solution alone which can be considered entirely adequate for very purpose. Each solution has quite definite indications. The injection treatment of varicose veins has passed the experimental stage and has been proved to

CHART V—This shows the red cell count of a case 1919-1928. T represents transfusion. Until liver therapy was begun, transfusion was supplemented by iron and arsenic therapy. The arrow shows where the patient began to take liver.

It is, perhaps, too soon to voice an opinion as to the permanency of the remission produced by liver fraction. Out of 25 cases who took the diet or extract, under constant supervision, 22 are now well after periods varying from one to three years. Two cases died as a result of progressive cord changes. One case refused to take adequate amounts of liver, and now shows rapidly advancing cord lesions though the blood picture has improved somewhat. Be this as it may, for the patient with pernicious anemia a new era has begun.

be a very rational form of treatment which should be accepted as supplanting other well recognized methods of therapy.—*J Am M Ass*, 1928.

The inventor of soda water was the Rev. Joseph Priestley, who was a renowned chemist and especially known as the discoverer of oxygen. Being persecuted in England for his political views, he sought refuge in Pennsylvania, where his experiments aroused the interest of Dr. Philip Syng Physick, of Philadelphia. The latter induced a local druggist to prepare carbonated water for his patients, adding fruit juice as a flavouring. Thus, in 1807, the soda water business came into being.

THE POST-OPERATIVE ACCIDENT*

BY GEORGE H. MURPHY, M.D., C.M.,

*Associate Professor of Clinical Surgery, Dalhousie University,**Halifax*

I HAVE so often referred to post-operative dangers and accidents in my efforts at clinical teaching, that it seems natural enough I should endeavour to work off a few thoughts on the subject on this occasion

CASE 1

Mrs F was fat and healthy, weighed 200 pounds, was forty years of age, and had a large umbilical omental hernia. She agreed to an operation which was performed in the usual manner. An attempt was made, after separating adhesions, to repack the herniated omentum into the peritoneal cavity. Failure, then removal of a piece of omentum and closure of the sac, with the peritoneum tending to stretch and tear under the strain. The sac is closed, but the pressure underneath is still pushing up into the open space, and you look uneasily at the anaesthetist who with a strange, unexplainable irony is letting the patient come out. One cough and you will be gathering up the fragments. It is an exciting moment. But finally the incision is closed, and one has made the best job in the circumstances. Catgut No 2, silkworm gut deep sutures, then a dressing strapped on with adhesive strips an inch wide, and a many tailed abdominal binder pinned on to help keep the dressings in place. The patient returned to the ward.

On the 7th day the deep sutures were removed, the wound was reported as healing well. On the 9th day patient took a coughing fit and something gave way. Being in the hospital at the time, I was hurriedly called. A number of intestinal loops were sticking between the tails of the abdominal bandage (now little more than strings gathered up in the middle of the abdomen). The incision was opened up. The omentum was bulging into the wound, some recently formed adhesions were now doing their full duty in preventing complete evulsion. This is the picture as one recalls the case. It is typical enough of that type where rupture of a post operative wound occurs from greatly increased intra abdominal pressure.

CASE 2

Sister M. was of the delicate type. Thin, pale, relaxed, anæmic, always tired, sleeping indifferently, nibbling at her food, while she kept about her work faithfully, she showed no energy, and was the very antithesis of bodily vigor. She had always been more or less so, but a bleeding fibroid had lately added a secondary anæmia to her physical imperfections.

With rest and careful nursing she was made an operative risk, and a subtotal hysterectomy was performed, from which she made a good recovery. Twelve days later, and two days following the removal of the sutures, in what seemed healing by first intention, she had a coughing fit, and the incision opened from end to end. When I got to her she was partly disemboweled. The many tailed binder was as usual gathered up in the middle of the abdomen like so many strings, and of no

protective value whatever. The nurse had covered the extruded intestines with sterile towels awaiting my arrival, so that things were not quite so bad as they could have been.

CASE 3

A man aged 72 years was operated on for acute appendicitis. The appendix had not ruptured, and there was nothing of note in the whole surgical entity, unless it were the marked senile sclerosis of his vessels. He became distended on the second day and was given a large soap suds enema with turpentine, without results. The distension was increased on the third day, without pain and vomiting, but with considerable distress. Those responsible for the conduct of his case decided that the bowels must be moved, and proceeded heroically to the task. One large enema after another was given, of soap-suds, turpentine, oxgall, magnesium sulphate, ammonia and molasses, with negative results, the patient's discomfort increasing proportionately to this therapeutic activity. On the fourth day severe abdominal pain and vomiting supervened, and all the signs of general peritonitis. In extremis the incision was opened for the purpose of stitching a tube in a loop of distended bowel, when it was found that the peritoneal cavity was half full of the enemata mixtures. The appendix stump was wide open, and the copious colonic floods had broken through into the peritoneal cavity as through a hole in the bottom of a rubber bag. Did the nurse not report syphoning back after each enema? She did, but good intentions and arithmetic are not always found combined. We are dealing with facts. Their exceptional character may hold some comfort, their reality remains undisturbed.

DISCUSSION

Cases 1 and 2 furnish the principal text for this paper. Case 3 must come in a class by itself, and I realize what a small part of the post-operative danger zone I shall cover in this effort.

The elements entering into the rupture of a post-operative abdominal wound are (1) increased intra-abdominal pressure, (2) feeble healing power of tissue, (3) suppuration, (4) defects in the mechanics of the incision and the wound closing, including defective catgut, etc.

Numbers one and two are illustrated in my first two cases, and they must bear the blame for the great bulk of this class of accident. Suppuration is often enough the cause of a weakened scar and consequent hernia, not often, of spontaneous rupture of wound and evulsion of viscera. The inflammatory process tacks the omentum and bowel down at the peritoneal margin of the wound, and, by thus plugging the opening, prevents a more serious disaster, not

* Read at the annual meeting of the Canadian Medical Association, Charlottetown, June 20, 1928.

the only time adhesions exercise a beneficent rôle

At staff meetings and clinical gatherings in general, when a case of wound rupture is reported, I invariably find that all discussion and speculation are directed to the fourth cause, and particularly to the question of defective catgut. Assuming that the wound is closed in the manner followed by 95 per cent of operators, I think this agent is the least of all the causes entering into the genesis of post-operative rupture. Catgut which stands the actual strain of holding together the layers, when stitching is completed, is quite likely to continue to do as much as we have right to expect of any suture in the circumstances. The deep intra-fascial silk worm gut strands are a great support, but they, too, have their limitations. There is no suture 100 per cent safe in such cases as the first. Two real factors are at work, (1) enormously increased intra-abdominal pressure, and (2) parietal tissue permeated with fat, which makes it brittle and easily torn. For this reason catgut is probably as safe as linen or silk, if not indeed safer, inasmuch as it is not so likely to cut through on account of its softer and stretching qualities. Split-muscle incisions and other anatomical side-stepping with the rectus and its sheath make for parietal security, but, for the average operator, have only a limited application.

The second case illustrates a type of post-operative rupture in which increased intra-abdominal pressure is not the main cause. There is no great pull on the suture line, and the skin and deep sutures are removed after what seems to be primary union. It is a feeble kind of repair, however, and is liable to let go. A sudden push on the abdominal wall from a sneeze or cough may be enough to open the whole wound. Distended intestines or anything which temporarily increases the intra-abdominal pressure may do the same. Scar tissue in such a patient matures more slowly, and calls for more careful support.

TREATMENT

By all the dicta of surgical common sense the treatment is prophylactic. Gathering up intestinal loops from among the bed-clothes is a bad business, particularly when you know it need not have happened. It is a real disaster, and unless skilled help is at hand, the patient and

all concerned are badly out of luck. The whole matter resolves itself into proper support of the abdominal parietes until the new scar may be depended upon to do its work.

Prof. Babkin, of Dalhousie University, has performed a number of experiments for me, in order to demonstrate some of the factors entering into what we have been calling intra-abdominal pressure. For the practical clinician perhaps the best concept of the whole mechanism is obtained by regarding the abdomen as a cylinder and the intra-abdominal pressure hydrostatic and distributed equally. Visualizing your lines of force with the patient in the recumbent position, the arrow points of the wound radiate from the centre in all directions, the sum total of the forces tending to stretch and rupture the abdominal cylinder. The lower end of the cylinder is closed and strongly reinforced with bone, fascia and muscle. Behind, the spine and the powerful contiguous muscles and ligaments present a practically unyielding structure along this section of the tube. The diaphragm and the belly wall are the yielding parts, and must furnish accommodation for any unusual push from within. The latter bears the real brunt, for the diaphragm, by its respiratory motion, acts something like a piston, modifying the pressure with each movement.

A newly closed abdominal wound is, therefore, among other things, a problem in physics. The forces drawing it apart are not concentrated on the edges of the incision, but extend all around the surface of the cylinder. The indication, then, is support all round, so that there is no unprotected spot in the whole abdominal wall. The best way seems to imitate nature's plan and supply an additional paries in the form of a heavy abdominal binder. It should be pinned on tightly and held below by wide strips of adhesive plaster extending over the outer surface of the thighs, and above by adhesive plaster extending along the sternum. An essential thing is that the binder have a grip on the thorax and on the pelvis. The mechanics of the binder is thus borrowed from the anatomical arrangement of the abdominal muscles and fascia, and in this way alone is it a real support. Without such attachments it will roll up from below, and down from above, by the patient's movements, and you will find, as I have so often observed, that the binder is little more than a few strings, if

it be the many-tailed type, or a very ineffective, puckered up band, in the middle of the abdomen Prof Babkin by artificially increasing intra-abdominal pressure in a number of cats showed experimentally the efficiency of this type of abdominal support

It has been objected that a binder tightly attached to the lower thorax embarrasses respiration, and adds to the post-operative distress of the patient With careful adjustment this need not be, and the splinting of the whole abdominal musculature lends a degree of comfort, such as obtains in a wounded limb after it is dressed and immobilized Every houseman I have had became a convert to this kind of post-operative bandaging, not only on account of its primary object in preventing rupture of the incision, but also on account of the patient's feeling of well-being as compared to his unbandaged neighbours in the ward It is hardly necessary to say that the bandage is applied on the operating table and the post-operative nurse knows her duty appertaining in the ward

Case 3 is quoted here to remind us that the human colon, wonderful piece of sewerage as it is, has nevertheless limits of endurance which may not be ignored. Have you ever on the operating table examined a colon in the condition usually described as post-operative ileus? What is it like? The bowel wall is so thin that you can hardly with the finest needle put a stitch in without perforating it It resembles nothing better than a blown-up rubber toy

balloon which is on the verge of rupturing It has no tone, it is a passive non-contractile tube that for the time has lost its power of responding to stimuli Surely the indication here is rest and not more exquisite forms of colonic torture Heroic efforts to move the bowels in such a case is flying in the face of physiological law, and clinical experience points a warning finger to just such a case as that quoted

If there is no response to a moderate sized enema it should be siphoned back, the patient given $\frac{1}{4}$ gr morphine, and allowed to sleep Often one finds that the bowels move after a few hours of rest without further enemata There seems to have been too much emphasis on the paralyzing effects of morphine on the bowel The precious rest it induces in such a case restores the whole physiological stance and knits up the unravelled threads of nerve exhaustion, so that the bowel comes back from a negative to a positive poise

In conclusion What are now pointed out are among the self-evident things, the trifles in connection with an abdominal operation One's observation is that it is the obvious, often, which is overlooked, and when one recalls even the exceptional instance where an excellent piece of surgical effort was wrecked on account of neglect of these trifles, he begins to wonder whether Michael Angelo's words might not be applied to our art as well "Trifles make perfection and perfection is no trifle"

THE COMPLEMENT FIXATION TEST, A MEANS OF FINDING CARRIERS OF DISEASE

BY A MACKENZIE FORBES, M D,

*Clinical Professor of Orthopædic Surgery, McGill University,
Montreal*

DURING the early spring of 1928 a mild epidemic of scarlet fever was reported in the Montreal Unit of the Shriners' Hospitals

The first case followed a burn The possibility of scarlet fever following this burn was known—indeed, so well known that the physician who rendered first aid to the patient employed anti-streptococcal serum as prophylactic treatment, although the patient had not been in contact

with anyone suffering from scarlet fever The second, third and fourth cases were definitely due to contact The later cases were not due to contact but were considered to be due to the presence of an unknown and unidentified carrier How could this carrier be found? Apparently science had shown no way

It was known that scarlet fever was caused by, or at least is coincident with, an infection

by one of the strains of streptococcus. The doctrine of transmutation is accepted by many bacteriologists. An infection by streptococci may be shown in a variety of forms, at one time as one condition, at another time by another condition.

About this time a young adult, who had no connection or contact with the Shriners' Hospital, contracted scarlet fever. How and where was not known. The patient was sent to the Alexandra Hospital, an institution devoted to the treatment of contagious diseases. In approximately one week after the diagnosis of scarlet fever was made in this patient, the mother became infected with erysipelas. Within two weeks after the mother's infection the first patient's brother became infected with what two prominent physicians called malignant tonsillitis. These physicians would have preferred to have called this scarlet fever as they knew of the sister suffering from this condition, but they felt their patient's condition did not conform to type. Within three weeks after the diagnosis had been made a fourth case of definite and typical scarlet fever appeared in the same family.

The epidemic of scarlet fever in the Shriners' Hospital was militating against the usefulness of that institution. The extraordinary history of the four patients mentioned above was an incentive to thought. Scarlet fever is due to a streptococcus or at least is coincident with a streptococcal infection. Streptococci might show their presence in various ways, in some cases causing different conditions. Yet streptococci are wholly or coincidentally the cause of scarlet fever, and without streptococci there can be no scarlet fever. Streptococci must be present as a precursor to scarlet fever. If the complement fixation test is of any value, surely this was a

time in which it should be found of service. For this reason Dr F. Green, the Serologist of the Shriners' Hospital was instructed to take the complement fixation test in the four persons who had been in closest contact with the several patients who had contracted scarlet fever during the epidemic in that hospital. He reported that three of these patients were negative to the complement fixation test. The fourth was positive to polyvalent streptococcus (three plus) and also to scarlatinal streptococcus. After the elimination of this person the epidemic was at an end. This bore out and seemed to confirm the hypothesis, but one swallow does not make a summer. For this reason it was decided that a systematic investigation should be made of the complement fixation test in scarlet fever. Dr Lawrence J. Rhea, Pathologist of the Montreal General Hospital and Dr H. B. Cushing, Chief Physician of the Alexandra Hospital were asked to aid in assuming that such might be carried out. Through the interest of these two it was made possible for Dr Green to make the complement fixation test in about forty cases of scarlet fever which were being treated in the Alexandra Hospital during the summer of 1928.

Dr Green has handed his report to the Chief Surgeon of the Shriners' Hospital. It was published in the last number of the *Canadian Medical Association Journal*. While this most interesting publication does not prove the contention that carriers of scarlet fever can be found by the use of the complement fixation test a promising piece of work has been initiated and it is hoped that it will lead to further investigation and further knowledge of scarlet fever, and the value of the complement fixation test as a means of finding carriers or disease.

Dextrose-Insulin Treatment of Shock.—Dextrose insulin treatment of shock is discussed by Preston A. Wade, New York. He says the use of dextrose intravenously with insulin subcutaneously in the treatment of shock gives results which, in this series, seem more satisfactory than those obtained in cases treated by saline or dextrose solution alone. Cases of traumatic shock treated early respond most readily to this treatment. Cases of post operative shock treated in this manner show marked improvement. The optimal dosage is 1,000 c.c. of 5 or 10 per cent dextrose with 1 unit of insulin to 3 Gm of dextrose. Beneficial results are usually ap-

parent after 800 c.c. of fluid has been injected. Cases of shock in which the blood pressure is decreasing toward the "critical level" (80 to 90) should be treated immediately before the rapid fall which usually follows, with symptoms of severe shock.—*J Am M Ass*, June 9, 1928.

In 1927 only four cases of small pox occurred in Germany. These had all been introduced from foreign countries. In the same year no fewer than 14,800 cases were notified in England and Wales.—*Brit M J* 1928, 11, 552.

NEPHROSIS IN CHILDREN*†

BY GLADYS L. BOYD, M.D.

Toronto

II LABORATORY FINDINGS

NEPHROSIS is one of those diseases in which the aid of the laboratory is not infrequently sought in order to establish a definite diagnosis. This is more particularly true in the chronic cases which often present a clinical picture identical with that seen in other types of kidney disease. Distinctive deviations from the normal are found in nephrosis, not only in the blood, urine and tissue fluids, but in the altered metabolism of the whole organism.

The most striking change in the urine of these patients is the large amount of albumen it contains. It literally 'boils solid'. Estimations of its protein content show that it constantly contains anywhere from one to thirty grams per litre. This excessive loss of protein may continue many months, or even years, without much variation in its severity. Closer study shows that this protein contains a larger proportion of globulin than is usually seen in cases of proteinuria. This relative increase in globulin has been shown by Kollert and Starlinger¹ to depend on the increased globulin fraction of the blood serum. None of the excessive protein excreted can be accounted for by hæmaturia, as the finding of the latter absolutely precludes the diagnosis of uncomplicated nephrosis.

The amount of urine voided during the early acute stages or in an exacerbation is usually small. It becomes excessive during the period in which œdema is being excreted. During quiescent periods or after recovery the daily excretion is normal. Nocturia rarely occurs except during diuresis. Wide variations in the specific gravity of the twenty-four hour specimen are seen, but in most cases it is between 1012 and 1015.

Microscopically the urine contains many casts, numerous white blood cells, and an occasional red blood cell. The casts are at first chiefly granular, both fine and coarse, and are very

numerous. Later, they become fewer in number and hyaline ones are more common. The number and nature of the casts in nephrosis is interesting in view of Christian's² contention that all casts are composed of material from the tubular epithelium, the granular ones being young and the hyaline old. Less easily demonstrable, but by many regarded as pathognomonic, are the doubly refractile bodies found in the urine in these cases. Such bodies are seen in other types of renal disease in which extensive tubular involvement is present as well as in nephrosis.

The urine calcium in two cases of nephrosis has been studied by Scriver³ who reports its concentration to be very low. As pointed out in a previous paper⁴ low urinary calcium is found in all forms of kidney disease and is not distinctive of any one type. Retention of both sodium and chlorine occurs⁵ in the hydropic stage of this disease as in other types of nephritis, but shows no peculiarity which would differentiate it from any other type.

The appearance of the blood is suggestive very soon after its withdrawal. The corpuscles separate more rapidly than normal and leave a serum varying from slightly turbid to distinctly milky in appearance. Fibrin clots form quickly, probably because of the great increase in the fibrin content of the serum which Kollert⁶ has shown to be present in these cases.

The results we have obtained in the study of the blood in some of our cases of nephrosis are given in Table I. The percentage of corpuscles present in the blood is usually less than fifty, often as low as twenty to thirty. The cell-volume tends to become lower as the disease becomes chronic and during periods of dropsy. The depression is not always directly proportional to the degree of œdema present.

The low protein content of the serum is constantly present. Epstein^{7,8} some years ago pointed this out and further demonstrated the alteration in the albumen-globulin ratio due to the relative increase of the latter. The combination of low cell-volume, low hæmoglobin and low protein would suggest blood dilution as the common cause of all three. Lindner, Lundsgaard and

* From the Laboratories of the Sub Department of Pædiatrics, University of Toronto, and the Hospital for Sick Children, Toronto, and the wards of the Hospital for Sick Children, under the direction of Alan Brown, M.B.

Unless otherwise indicated, figures represent milligrams per 100 c. c. of blood except in the case of total base which is given in terms of c. c. of N/1

Van Slyke⁹ have shown however, by estimating protein per body weight, that such is not the case but that actual depletion of serum protein is present. Brown and Rowntree¹⁰ further demonstrated in the three cases they studied that the blood volume was normal. No close relationship is demonstrable between the degree of œdema present and the blood protein but the tendency is toward an increased blood protein after diuresis. Possibly the altered ratio between the albumen and globulin is more closely associated with the degree of œdema present, as Lindner *et al* have shown that this ratio falls when œdema is present in nephrosis.

Lipæmia of some degree is a sufficiently constant finding to justify the name lipæmic nephritis, frequently given the disease. It is not the only lipæmic nephritis however. Hypolipidæmia was present in only one of our cases, a terminal one of syphilitic origin. The cholesterol shows a relatively greater increase than the total fat. We agree with Harrison¹¹ however

that little help in differentiating between nephrosis and other types of nephritis with tubular involvement is given by the determination of cholesterol. The degree of turbidity of the sera in these cases appears a better indication of its fat content than it does in cases of diabetes. Below are the maximum, minimum and average figures we obtained in the study of the blood fat and cholesterol in these cases. The determinations were made by Bloor's method.

	Blood fat	Blood cholesterol
Maximum	1938	830
Minimum	434	140
Average	797	298

There is usually no evidence of retention of nitrogen and products in nephrosis, indeed the absence of such is usually regarded as necessary in making the diagnosis. Exceptions to this rule do however occur as a terminal event in otherwise typical cases which have run a chronic course. In such cases creatinin is most markedly increased. Nitrogen retention probably occurs

in cases which have been typical nephroses but have developed a chronic interstitial nephritis secondary to their nephrosis

The blood sugar is usually normal or low. Hyperglycaemia was present in one of our cases and has been reported in another by de Toni¹²

The plasma chlorides tend to vary with the degree and the stage of oedema present. Generally speaking, during the acute or hydræmic stages of the disease hypochloræmia is found. As the disease becomes chronic or recovery ensues they reach a normal or high level but are quickly lowered if for any reason oedema develops again. The plasma sodium is normal. Phosphates are normal unless acidosis is present. Magnesium is constantly at a low normal level and potassium at the upper limit of normality. The variation in the total base-content of the blood is not striking but it is usually about the lowest limit of normal, or actually decreased.

Clausen¹³ and Clark¹⁴ have demonstrated a marked lowering of the surface-tension of the plasma in nephrosis. Some reduction is present in cardiac oedema but is not nearly so marked.

Clausen finds this surface-tension reducing substance in the urine as well as the blood.

Characteristic changes are also found in the fluid which accumulates so rapidly and persistently in the thorax and abdomen. The turbidity of this fluid is so great as to suggest pyogenic infection. Cultures however are sterile and the sediment consists of broken down endothelial cells and amorphous material. The turbidity is due to the increased fat content. The specific gravity, salt and protein content of these fluids, is low.

The results obtained when the renal functional tests were done on thirteen of our cases are given in Table II. The most constantly present and valuable diagnostic aid is the normal blood pressure. Increased systolic blood pressure excludes nephrosis as the cause of the symptoms present, except in those rather rare cases in which the disease has a sudden stormy onset with cerebral oedema. The rise in such cases may be great but is necessarily of short duration. Persistent elevation of blood pressure never occurs in nephrosis.

TABLE II
FUNCTIONAL TESTS IN NEPHROSIS

*Phenolsulphophthalein is the percentage of the drug injected excreted in 2 hours. †Under concentration test the variation in specific gravity and its height in the night urine are given. ‡Under water test the lowest specific gravity obtained and the percentage of the intake excreted in the first 4 hours are given.

¶ The phthalein test appears to be an unfair test of renal function in this disease and is therefore of little value. The response to the injection is almost invariably poor and we feel that extrarenal factors, such as œdema and altered capillary permeability, prevent its quick absorption and that its slow excretion is therefore no indication of impairment of renal function.

The concentration test, simply done by determining the specific gravity of two hour urine specimens, while the patient is on a dry diet, offers the most valuable aid of any of the tests in making a prognosis. Functional deficiency in this case is usually most noticeable in the failure of the patient to concentrate his night urine as well as usual. Persistently low specific gravity of the night urine and decrease in its daily variations warrant a prognosis of chronicity, whatever the clinical condition of the patient suggests.

Water tests usually demonstrate some delay in the ability of the kidney to excrete water and a less marked depression of its function of diluting. They are of little value in making a prognosis as complete recovery is quite possible in spite of poor response to the test.

The excretion of added sodium chloride is always poor, and the test should not be done in these cases as it not infrequently initiates a relapse.

As pointed out in a previous paper, the laboratory furnishes some evidence of the systemic nature of the disease as demonstrated by the reduction of the basal metabolic rate. This depression of basal metabolism has been noted by a number of observers and is of too great magnitude to be accounted for by the œdema present. It is a constant finding in those cases of nephrosis studied by this means.

SUMMARY

1 The characteristic changes in the urine in nephrosis are, the large amount and the unusual nature of the protein it contains, the absence of gross hæmaturia, the presence of large numbers of casts and frequently white blood cells and of a doubly refractile body.

2 The distinctive findings in the blood are, its low protein content, altered albumen-globulin ratio, lowered surface tension, more or less lipæmia especially cholesterolaemia, and the practical absence of any evidence of nitrogen retention.

3 Serous effusions present suggestive evidence of the presence of the disease by their turbidity, low protein and salt content, and increased fat.

4 The blood pressure in uncomplicated cases is always normal or low.

5 The basal metabolism is depressed.

6 The concentration test is the only one of the functional tests that gives any reliable aid in making a prognosis.

Case of Hæmaturia from Shoe Dye Poisoning—

O J Schmitt cites the case of a boy, aged 17, of athletic stature, who wore freshly dyed shoes for seven hours, when cyanosis and headache made their appearance. When seen, three hours after onset of the symptoms, his face and finger nails were deeply cyanosed and he complained of severe frontal headache. The rate and character of the pulse, respirations and temperature were normal. He was advised to bathe the feet repeatedly in water, to take a sponge bath and a purgative, to drink large quantities of water, to put an ice cap on the head, and to rest near an open window. The cyanosis and headache had entirely disappeared by the next morning, but the patient was advised to remain

quiet. The urine the following day was a clear, dark amber, acid in reaction, and with a specific gravity of 1.025. Two days later the patient complained of dysuria and bloody urine. The blood pressure was 124 systolic and 80 diastolic, the red cell count, 4,120,000, leukocytes, 11,850, and hæmoglobin, 75 per cent (Tallqvist). Alkaline drinks, together with a bland diet and rest in bed, were ordered, and in the following two days the pain gradually disappeared, the urine resumed its normal clear amber colour, and at the end of five days no red blood cells could be found microscopically. The analysis of the dye as reported by the chemist showed aniline as the source of poisoning.—*J Am M Ass*, 1928, xci, 726.

THE CALCIUM AND PHOSPHORUS CONCENTRATION IN THE INTESTINAL CONTENTS OF RATS IN RELATION TO RICKETS*

BY ANGELIA M COURTNEY, B A, FREDERICK F TISDALL, M D,

AND ALAN BROWN, M B

Toronto

IN the present paper are reported the results of an investigation of the concentration of calcium and phosphorus in different sections of the intestinal tract of rats fed on McCollum's rachitogenic diet 3143¹ and of a group of rats on a normal diet. The hydrogen-ion concentration of the different sections was also determined. The rats were divided into two groups, one kept inside in the dark and allowed to develop rickets, and the other exposed to the rays of the fall and winter sun, which produced a slight but definite antirachitic effect.

Each week a number of rats, twenty-five to twenty-seven days old, were placed on the rachitogenic diet, and a group of them exposed to the sun's rays each day for two hours. After four weeks the rats were killed under ether anaesthesia and immediately thereafter dissected and the intestinal contents removed by gentle pressure. The intestine was divided for this purpose into five portions: A, the upper half of the small intestine, B, the lower half, C, the caecum, and D and E the upper and lower halves respectively of the remaining large intestine. If during anaesthesia faeces were dejected these were collected and formed a sixth portion, designated F.

A composite sample was made of the contents of each of the six sections of the intestines of all the rats in a single cage. After withdrawal of a small sample for estimation of hydrogen-ion concentration each total emulsion was dried to constant weight on a steam-bath and the dried material was used for calcium and phosphorus determinations. On five occasions the hydrogen-ion concentration estimations were made on the material from each rat separately. This was done in order to learn what was the range of variation for the rats in the same cage. For the most part there was no marked variation, but occasionally one rat in a cage would show en-

tirely different pH values from all the others in the same cage.

Hydrogen-ion concentration was estimated by the Levy, Rowntree and Marriott colorimetric method, as applied to faeces by Tisdall and Brown².

For the calcium and phosphorus determinations Tisdall's micro-methods for use with blood serum^{3,4} were modified for application to dried material. For estimating total phosphorus the dried substance was ashed with a mixture of sulphuric and nitric acids in a large Pyrex test tube with the careful employment of heat from a micro-burner. The solution was made to volume, an aliquot part almost neutralized with concentrated ammonia water, and the original method for serum followed.

The procedure for estimating calcium and inorganically bound phosphorus is as follows. Place the weighed samples in 15 c.c. graduated centrifuge tubes and add to each about 5 c.c. of a six per cent solution of trichloroacetic acid. Mix thoroughly and extract by tapping the tubes at intervals for about fifteen minutes. Centrifuge and pour off the extract into small volumetric flasks (20 to 25 c.c.). Repeat the process with the residues. Only two extractions are necessary to remove completely the soluble calcium and phosphorus. Make the extracts to volume, and determine calcium and phosphorus in aliquot parts.

A characteristic condition of the intestines and their contents in the three groups of rats was observed during the dissections. There was little apparent difference among them in respect to the contents of the small intestine. In all, the upper part was filled mainly with mucus and the lower with mucus intermingled with small quantities of faecal matter. The contents of the large intestine showed distinct differences in the three groups. In the rats on normal diet the caecum was always large and filled with faecal material of a soft and homogeneous consistency, while in the rats on the rachitogenic diet the caecum was

*From the Laboratories of the Sub Department of Pediatrics, University of Toronto and of the Hospital for Sick Children, Toronto.

small and the contents scanty. The contents below the cæcum were in separate small masses in all the rats, but there was a marked difference in the consistency of these masses in the three groups of rats. In the rachitic rats the contents were rather hard, in those on the rachitogenic diet exposed to sunshine they were soft, sometimes almost watery, while in the normal rat they were firm but distinctly softer than in the rachitic rats. In both groups of rats on the rachitogenic diet there was more or less distension with gas in the neighbourhood of the cæcum. In these groups also the intestinal walls were thin and fragile, in contrast with the substantial condition of the walls in the rats on normal diet.

In the tables the calcium and phosphorus values are expressed as grams per gram of total solids. In the consideration of these values it must be kept in mind that they represent the concentration of calcium and phosphorus, not the actual amounts present. Under the conditions of the experiment it was not possible to establish any relationship between amount of intake and amount of intestinal contents. Accordingly a strictly quantitative collection of the material was not attempted.

Table I includes for each of the two groups of rats on the rachitogenic diet and for a third group on a normal diet hydrogen-ion concentration,

total calcium, and total phosphorus for the six sections separately.

The total calcium and total phosphorus values for the rats on a rachitogenic diet show no essential differences between the rats kept inside and those exposed to the sun, with the one exception of the calcium content of the cæcum which was markedly higher in the rats kept inside. This striking difference will be discussed in connection with Table III.

The differences for both calcium and phosphorus between the rats on the normal and those on the rachitogenic diet are presumably largely due to the differences in the calcium and phosphorus intake as shown in Table II.

TABLE II

CALCIUM AND PHOSPHORUS CONTENT OF NORMAL AND OF RACHITOGENTIC DIET, GRAMS PER GRAM OF TOTAL SOLIDS

	Calcium	Total Phosphorus	Inorganic Phosphorus	Organic Phosphorus
Normal diet	0083	0060	0023	0037
Rachitogenic diet	0107	0033	trace	0033

The hydrogen-ion concentration shows significant differences in the three groups. The normal rats have an acid reaction in the beginning of the small intestine and the reaction becomes more alkaline throughout the tract. The rats on the rachitogenic diet, whether exposed to the sun or not, have a more alkaline reaction at the beginning of the small intestine than the normal rats. With those kept inside the reaction begins at once to increase in alkalinity. On the other hand in the rats exposed to sunshine the contents remain at practically the same reaction throughout the course of the intestines. These findings are in general agreement with those reported by Tisdall and Price⁵, which were obtained from rats exposed to sunshine during the summer months.

In Table III the phosphorus values are expressed as inorganically and organically bound phosphorus. This table also shows the amounts of Ca and inorganic P in combination as tricalcium phosphate and the excess of calcium or of phosphorus, as the case may be, over the amount bound as tricalcium phosphate. This distribution was assumed because according to the work of Holt *et al.*⁶ on the solubility relationship of calcium and phosphorus compounds to hydrogen-ion concentration, the pH values found were throughout too high to admit of the presence of the acid phosphates in appreciable quantities.

Considering the calcium bound as tricalcium

F	8	0093	0467	8	0048	0	8	0072

phosphate, it is seen that in the small intestine the concentration is practically identical on the normal and the rachitogenic diets. This might reasonably indicate that practically all food has been absorbed or passed on into the large intestine and that the values are really those for the intestinal secretion. When the large intestine is considered, a comparison between the results obtained with rats on the normal diet and those on the rachitogenic is obviously of little value from the viewpoint of salt excretion since the intake of calcium and phosphorus was so different on the two diets. The two groups on the rachitogenic diet show no marked differences as regards calcium bound as tricalcium phosphate. On the other hand the amount of calcium not bound as tricalcium phosphate is much lower in the cæcum of the rats exposed to sunshine than in those kept inside. This may be taken as an indication either of increased absorption in the preceding small intestine or of a lessened excretion in the cæcum of calcium in some other form than tricalcium phosphate. We feel that this observation, that the difference in the calcium concentration in the large intestine of the two groups lies not with calcium bound to phosphate but in some other calcium compound is of considerable value, as it indicates that the calcium

absorption or excretion in relation to rickets may not be so intimately associated with the phosphorus as is now considered to be the case by the majority of investigators.

A consideration of the phosphorus concentration in the large intestine, whether in the inorganic form bound to calcium, or in the organic form, shows no essential differences between the rats exposed to sunshine and those inside. This lends further support to the view suggested by the calcium findings.

SUMMARY

1 Normal rats have an acid reaction in the beginning of the small intestine and the reaction becomes more alkaline throughout the tract. Rats on the rachitogenic diet, whether exposed to the sun or not, have a more alkaline reaction at the beginning of the small intestine than the normal rats. With those kept inside the reaction begins at once to increase in alkalinity. On the other hand in the rats exposed to sunshine the contents remain at practically the same reaction throughout the course of the intestines.

2 The total calcium content of the cæcum of rats fed on McCollum's rachitogenic diet and

kept inside was much higher than that of rats fed the same diet and exposed to sunshine

3 The calcium bound with phosphorus was essentially the same in the cæcum of both groups of rats fed on the rachitogenic diet

4 The difference in the calcium concentration in the cæcum in these two groups is thus due to calcium not bound with phosphorus

5 No essential difference was found in the phosphorus concentration in the large intestines of the two groups of rats fed on the rachitogenic diet

6 These observations suggest that the calcium

absorption or excretion in relation to rickets may not be so intimately associated with the phosphorus as is generally considered

CONSTIPATION, ITS CAUSE AND CORRECTION

By N A PAGE, M D

Department of Internal Medicine, Lockwood Clinic, Toronto

THERE are few, if any, better definitions of constipation than that given by Ludwig Kast,¹ in which he has expressed himself thus "Constipation is a disturbance of intestinal function characterized by the insufficient or abnormally retarded elimination of intestinal contents" It is my intention to deal only with the so-called functional or idiopathic constipation, though it should always be remembered that careful consideration should first be given to determine whether or not the case in point is a member of this large group, or whether actual disease underlies the condition If any doubt remains in the mind of the doctor, a careful elimination should be made of extrinsic causes, such as pressure, or organic diseases of the type of cholecystitis, chronic appendicitis, etc, to which constipation is reflex Failing this, proctoscopic examination should be made and complete x-ray pictures be taken of the stomach, small bowel and colon

The question of the importance of this symptom to the welfare of the patient next arises Here we find a great diversity of opinion among authorities Some claim that it is of the utmost importance, since it underlies so-called auto-intoxication, others believe that it bears directly on essential hypertension, while still others associate it with hypotension There are those, on the other hand, who think that unless constipation occurs to a degree of severity approaching obstipation, it has little, if any, significance Whatever one's opinion on the subject may be,

the question cannot be disputed that, in the mind of the layman, constipation assumes a most important rôle Our daily newspapers are filled with advertisements for various patent preparations alleged to relieve or cure the condition This indicates the position it occupies in the mind of the public And, since we are, in a sense, the servants of the public, it is our duty to endeavour to deal with the condition intelligently

Out of three hundred consecutive cases reviewed there were found to be one hundred and twenty-six who gave constipation as one of their complaints, that is, forty-two per cent In addition to these, there were thirty-seven who, on being questioned, stated that they had had some trouble in this regard for many years Thus, if such are included in our figures, the percentage is raised to fifty-four

DIAGNOSIS

In diagnosing constipation the first essential is to ascertain whether or not the patient is truly constipated Indication of this is found in the stools The truly constipated will give a history of passing hard, dry faeces Many patients are found who believe themselves to be suffering from this condition, who, on being questioned, report the stools as of normal consistency This is not true constipation since, if there is a delay in the passage of the food residue in any section of the intestinal tract, fluid content must be lost, with the result noted A more

accurate estimation may be arrived at by the administration of carmine, given in ten-grain capsules, the evidence of the excretion of this dye will occur in the normal individual within twenty-four to forty-eight hours and will be complete in seventy-two hours

The old classification, spastic and atonic, is discarded by Erdheim,² though it would seem that it is still of service, if one remembers that there may be, in the one patient, a combination of the two types and that each large division is again subdivided into several branches. The stimulation of the vagus nerve results in increasing peristalsis which, peculiarly, may produce either diarrhoea or constipation, depending on the severity of the stimulation, since it may interfere with the normal peristalsis or may accelerate it. Stimulation of the splanchnic nerve, on the other hand, inhibits peristalsis. This nervous control is unquestionably influenced by the hormone derived from the mucosa of the intestinal tract, and it is probable that the spleen may also contribute further control.

Either type may be most accurately and readily diagnosed by a barium series, the atonic being shown by the large, somewhat relaxed colon with deepened haustra, the spastic by the small constricted lumen. Irregularities, however, may occur, with relaxation in one part followed by constriction without organic obstruction in another. This will complicate the picture and the treatment. It is neither desirable nor necessary to submit all patients to this expensive mode of diagnosing their condition. If, however, any possibility of organic disease exists, it is perhaps not out of place for us to stress again the importance of these measures.

The spastic type is usually found in the highly strung, so-called neurotic, individual, and in the great majority of these, the sigmoid colon, and sometimes even the entire colon, may resemble on palpation a firm, rope-like mass which is invariably tender. The atonic type, on the other hand, is usually found in the otherwise healthy individual, or in those showing characteristics of mild hypothyroidism (the lethargic variety). The colon of such is neither palpable nor tender. Boborygmus is often noted and there is usually a lack of tone in the abdominal muscles, with a resulting visceroptosis. One is too prone, however, to diagnose visceroptosis as the cause of the associated constipation. Ludwig Kast feels that such is never the case, though it may occasionally be an irritating factor. Even

radiologists now hesitate to consider displaced or slightly kinked colons to be of great importance, without signs of associated disease producing this abnormality.

Rectal constipation is often allotted a separate classification, though it is actually an atonic form, readily diagnosed by proctoscopic examination, the rectum being found lax, distended, and usually full of hard, faecal masses. This may be caused by repeated enemata, by the presence of hæmorrhoids, with resulting tenesmus and consequent suppression of the act, first conscious and finally subconscious, or it may be predisposed by a congenital tightness of the anal sphincter.

Before dealing with the cases under consideration one might mention the possible complications of any one of these three forms. Colitis may result from damage to the intestinal wall, this alternating with constipation, though in such cases malignancy must be watched for particularly. Fissura in ano, pruritus ani, and hæmorrhoids must be added to the list. When one remembers that colonic ulcerations may in turn serve as a focus which may act like other foci in the body (though showing an apparent preference for the abdominal organs, the gall-bladder, appendix, kidneys, etc.) one is impressed still further with the importance of this subject which is too often lightly dismissed by many of us.

ETIOLOGY

Considering in somewhat greater detail the etiology of constipation, there are numerous factors to be considered, many of which are the direct result of our civilization. Even in prehistoric days when, in the process of development, man assumed the upright posture, gravity was given a greater chance to favour ptosis. This was further aided in a later stage of our existence by the increasing sedentary nature of our lives. But, as before explained, many patients with a marked degree of visceroptosis enjoy normal evacuations, and so this must be considered as only one possible link in the chain. In women, pregnancy would seem to produce an increased tendency to this complaint. Here, three factors may play a part, first, the general laxity and resultant weakness of the abdominal musculature, secondly, the common occurrence of hæmorrhoids at the time of, and preceding, labour, with the resultant tenesmus and subconscious suppression of desire, and, thirdly, the mechanical interference during the middle and latter months, with

subsequent habit formation. Lack of exercise, too, plays a part, though it is questionable if it is so great a factor as is popularly believed. Patients in hospital may be controlled without catharsis by a rational diet-combination of carbohydrates and fats. It is claimed, on the other hand, that postmen and policemen are inclined to constipation. Since none of such is included in our series we cannot contribute any figures on this point. However, we do find many farmers suffering from constipation. Their diet, as a rule, is adequate and wholesome, somewhat rough in type, supplying one would think, sufficient volume and residue, nor is there any lack of exercise in their lives. But, on investigating their history further, we find that on leaving the house in the morning they often spend the entire forenoon in the fields and on their return the optimum time for evacuation has passed. This might likewise apply to postmen and policemen.

The drinking of water is also of importance, though experience does not lead us to believe it to have so marked an effect on the bowel as is generally supposed. It is, without question, an excellent diuretic, and serves its part in carrying away the waste products of metabolism, but, few cases of constipation are cured by its use. A glass of hot water, taken on rising, may serve to stimulate intestinal peristalsis, following this the morning meal adds its effect, and the after-breakfast habit is in this way influenced by the morning draught.

It is claimed that blood pressure has a relation to colonic stasis. Alferez,³ however, in reporting one thousand cases of essential hypertension, finds that only forty-six per cent give this symptom, this being no higher than the percentage found in this clinic of all patients. Low blood-pressure, likewise, has little demonstrable relationship to constipation. Only thirty-nine per cent of the cases here reported showed a systolic blood pressure of less than one hundred and fifteen, thus leaving the great majority of patients well within the normal range.

Sex also seems to be of importance, since forty-six per cent females, compared with thirty-seven per cent males, complained of constipation. No doubt the difference is explained, to some extent at least, by the process of child-bearing and labour.

Age, too, is a contributing factor, due in part to a changed manner of living, but principally to the physical changes that are undergone with

the advance of years, the weakening of the musculature, and the general loss in elasticity of the body tissue. Unfortunately, our group does not illustrate this point, as the majority of these patients varied in age from twenty-five to fifty-five years of age.

Some members of the medical profession feel that the endocrine glands play an important part, their secretions acting directly through the nervous mechanism. Of these, the pituitary and the thyroid seem to be the most important, and though at this time endocrinology is in its infancy, and the tendency is to find in these the hypothetical source of any trouble of which the true nature is veiled in obscurity, yet we are forced to admit the possibility of this influence. All cases of intestinal stasis do not show signs of glandular hypofunction, but one rarely finds a patient giving evidence of hypothyroidism, by lowered basal metabolism, slow pulse, low blood pressure, etc., who does not include in his list of complaints faulty evacuation of the bowel. It is also true that such patients respond marvellously to treatment directed along these lines, the administration of the glandular extract often being in itself sufficient to control the condition after the preliminary restoration of normal function.

The last factor to be considered is one of the greatest, if not the greatest contributing cause of constipation, that is, the practice of habitual catharsis. Mothers, anxious for the welfare of their children, start the regular administration of pills, castor oil, salts and similar laxatives at an early age. In many cases it is a hard and fast rule that Friday night is the regular time for such medications, entirely unmindful of any need for such measures. Thus, the habit is established in the young, and too often, as time passes, it apparently becomes a necessity. Cathartics are perhaps among the most constipating medications that one can take and should be used only as emergency measures. The same remark applies to enemata. This practice is fortunately not so widely indulged in in Canada as in many parts of the United States. Enemata have their purpose, but to educate people to believe that they require "internal baths," as they are called by their ardent supporters, as frequently as they require external bathing, is absolute folly.

SYMPTOMATOLOGY

Discussing the symptomatology of stasis with

any degree of accuracy is a matter of some difficulty, and yet there is a certain sameness that occurs with persistence in such cases, making it safe to assume that there is a definite relationship between these common features and constipation. Such are—A history of fullness after meals, belching of gas a variable time after food, vague abdominal discomfort, often dull, aching pain in the lower left quadrant, sometimes a similar discomfort in the right lower quadrant, suggesting on examination chronic appendicitis, though no history of an acute attack is obtained. Headaches are common. Anorexia, foul breath, coated tongue, occasional nausea, are complained of, and sometimes regurgitation of food after meals. Abdominal cramps, borborygmus, pain in the back, etc., may be added to this list. In practically all cases where the gastric acidity is normal and there is no associated organic disease, these symptoms greatly improve or disappear with proper control of the bowels.

The complaints generally associated with constipation, such as tiring readily, exhaustion, nervousness, lack of reserve energy, dizziness, palpitation, etc., are not, however, so amenable to treatment. Constipation is almost invariably found associated with migraine, and is also present in the majority of cases of epilepsy. When the normal intestinal function is restored there is usually some improvement in the symptom complex, but as it can be classed only as an improvement, one is forced to conclude that it is but one of several factors at work.

TREATMENT

And now, in conclusion, a word must be said as to treatment. No set rules can be applied as a routine, since the procedure to be adopted must of necessity vary materially with the type and with the cause in each individual case. We have indicated certain measures throughout. Unquestionably, a normal healthy life is essential, paying particular attention to the regularity of one's habits, to meals and hours of sleep. A glass of water on rising has certain benefits, the mechanism of which we previously explained. The time for going to stool should be definite and the optimum is, without doubt, immediately following the morning meal. The position at stool is important, the knees well flexed on the abdomen. The diet is most essential. There are few patients with functional constipation who will not in time be able to carry on normally on a diet rich in carbohydrates

such as fresh and stewed fruits, figs, prunes, green vegetables, sugar, etc. Roughage may be obtained through whole wheat bread, bran muffins, etc. As a rule, tea, cheese and excessive meat-eating should be avoided. Excesses of fatty foods should likewise be eliminated, though it is interesting to note in this regard that Florence H. Smith⁴ reports excellent results in the treatment of constipation by high fat feedings. Her prescribed diet consists in protein 66, carbohydrates 164, fat 224, which she states will control even the most persistent cases in three to five days, though she reports that a very occasional patient has resisted treatment for as long as three months. Psyllium seeds, flax seeds, bran, etc., are of marked benefit in many cases, supplying the necessary bulk for stimulation of peristalsis. Yet, these should be introduced with care in the case of patients who have been on soft bland diet for long periods, as they may by this sudden radical change be markedly upset, and the co-operation and confidence of the patient is lost before treatment is well inaugurated. Cathartics, enemas, etc., should be discontinued, though in the most obstinate cases it is impossible to suddenly accomplish this. A little cascara may be given primarily, but the importance of gradually diminishing this cannot be over-stressed. Small retention oil enemas are often useful in the presence of hard, impacted feces, such as are found in rectal constipation. Soap-suds enemas of the usual type should only be used when absolutely necessary.

Massage, while used by many, does not find a supporter in Soper⁵. The purpose of this massage is to stimulate peristalsis. It is questionable if it accomplishes this, and undoubtedly the intake of food forms a much more reliable stimulant. It is, however, still employed by many physicians, the massage following the lines of the colon and being of a gentle rotary nature. Even by this procedure, there have been several cases reported in which damage to underlying diseased organs has resulted. However, we are presupposing that such disease has already been carefully eliminated.

Mineral oil is our greatest ally in combating constipation, being second only to dietetic measures. This, too, however, has its disadvantages, producing at times a seepage from the rectum which is found embarrassing to the patient. Fortunately, however, in its emulsified form this disadvantage is largely overcome, and we have in many cases found it of the greatest value com-

bined with the old-time remedy, agar-agar. Several patients have recently asked whether there is any danger in the use of mineral oil as a causative factor in the production of cancer. This idea must have been obtained from some published article, but we were unsuccessful in finding anything dealing with this subject. Perhaps the idea arose from a paper by Robert Gibson⁶ in which he pointed out that seepage may produce an eczema about the anus which might in time assume a cancerous nature. However, he cited no case in which it had done so, and, as the seepage may be controlled by the use of the emulsion, it would seem safe to overlook this theory as a possible contra-indication until more material evidence is produced to support it.

In conclusion, certain drugs may prove useful

in chosen cases. Belladonna is an excellent adjunct to the treatment of the spastic type, similarly, bromides and luminal are found to have a favourable effect on the psycho-neurotic patient, pituitrin is useful in those giving signs of atonic constipation, thyroid extract, which we merely mention, having dealt with it previously, and olive oil which is useful in the undernourished type, in the absence of any suggestion of an associated cholecystitis.

LEAD POISONING IN BRONZE FOUNDRIES*

By FRANK G. PEDLEY, M.D., D.R.P.H., AND GORDON SPROULE, M.Sc.,

Montreal

THE occurrence of lead poisoning among bronze founders cannot be very uncommon, yet the medical literature seems to be devoid of references to the subject. The United States Bureau of Labor Statistics, in its *Bulletin No 306*,¹ which lists in tabular form the various occupations and their hazards, has not infrequently been accused of excessive zeal in associating lead poisoning with occupations where its occurrence is of academic interest only. This *Bulletin* mentions the hazard of lead poisoning in brass foundries, but does not include bronze foundries in the lead group. We have searched most of the text-books on industrial hygiene, and the various medical indexes, but have failed to find any reference to lead poisoning among bronze founders. This is all the more strange since many laymen and quite a number of physicians are well aware of the hazard. During the past six months we have had the opportunity of seeing some ten cases of lead poisoning among bronze founders, and have seen a number of other bronze founders who showed very suggestive signs of lead poisoning, either in the Burtonian line or in the presence of basophilic stippling.

The clinical histories of these ten active cases present little of note. They were all more or less typical cases of plumbism, showing the blue line in the gums, stippling of the red blood cells, and lead in the urine, and complaining of severe abdominal pain and constipation. Several of them were considered sick enough to be admitted to the wards of the Montreal General Hospital, but none showed any of the distressing complications of palsy or encephalopathy. Most of the cases returned to their old work when their symptoms had been relieved and they had been placed on a lead-eliminating régime for a few weeks.

True bronze is an alloy of copper and tin, but other elements may enter into the alloy, such as aluminum, phosphorus and lead. Not infrequently brass, containing no tin at all, is loosely spoken of as bronze. Books to which the medical reader has ready access do not speak of lead as a common constituent of bronze. The usually reliable *Encyclopædia Britannica* mentions the possibility of traces of lead in statuary bronze, but does not refer to its presence in other bronzes. As a matter of fact lead is a common constituent of bronze, particularly of the so-called "railroad bronze," where its presence, at first accidental, is now considered very desirable. The piston packing-rings of locomotives contain

* From the Industrial Clinic, Montreal General Hospital, and the Department of Metallurgical Engineering, McGill University.

nominally 50 per cent lead and 50 per cent copper. They are usually called bronze. Bearing metal contains from 12 to 20 per cent lead, because of the anti-frictional qualities of the metal. Roast and Newell,² in a recent paper, give the analyses of several bronze bearing-Metals. Two of these contain 15 per cent of lead and one 10 per cent. For the car journal bearings of the Pennsylvania Railroad at least 13 per cent lead is called for and one special high lead bronze contains 25 per cent.¹¹ A typical analysis of railroad bronze (supplied by the Operation Department, Motive Power and Car Equipment Sections, Canadian National Railways) is as follows

	Per Cent
Lead	15 to 22
Tin	5 to 7
Total of lead, tin and copper, minimum	97
Remainder, including zinc, maximum	3
Remainder, excluding zinc, maximum	1

EXPERIMENTAL CONSIDERATIONS

That molten metallic lead gives off visible fumes when at an "orange heat" or above it is obvious enough to those who work with it, but it seemed to the authors desirable to obtain some quantitative evidence on the question of its volatility. Reference tables give the boiling point of pure lead variously as from 1550°C to 1640°C. Even the lower and more probable of these temperatures is a dazzling white heat, far beyond any temperature to which any lead-bearing alloy is ever heated, and beyond the temperatures at which the products of lead smelting furnaces are produced. Also, according to Schenck and Dean,³ the vapour pressure of lead falls very rapidly with the temperature as shown by the following figures

Pressure, mm Hg

760 100 50 10 1 10¹ 10² 10³

Temperature, deg C

1640 1360 1290 1130 960 820 710 620

Nevertheless, as mentioned above, if lead is heated to a temperature of 900°C or more, and if the lead oxide formed is continuously removed, as by absorption in a porous vessel, or by a blast as in the process of cupellation, the lead is seen to produce fumes.

A similar condition exists during the casting of bronzes that contain much lead. These alloys have a high melting point, because the melting point of the copper is only slightly lowered by the lead and the comparatively small amounts of

tin and other metals that may be present. Indeed, the copper-lead mixture may be described as more of an emulsion than a true alloy, so slight is the affinity between these metals, and special skill is required to get good results in the founding of high-lead bronzes. The pouring temperature of these bronzes is from 1040°C to 1150°C.

While being melted the bronze is in a closed furnace and, further, the metal in the crucible is covered with a slag that checks volatilization, but while the castings are being poured the metal in the crucible or ladle is kept skimmed more or less clean, and the stream of molten metal itself is continuously clean. Thus we have conditions quite similar to those under which cupellation is conducted, and fumes or "smoke" of oxidized lead vapour proceed from the hot bronze and circulate through the foundry, unless suitable draft arrangements are provided to remove them.

The boiling points of copper and tin are both much higher than that of lead, namely 2310°C and 2275°C respectively, and the bronzes in question are free or very low in zinc, (which is volatile), so it seems evident enough that we are getting lead fumes under the circumstances described. However, to get a quantitative idea of what the observed smoke represents, the following preliminary experiments were carried out.

Experiment A—Two grades of standard lead bronze were used: (1) railway journal bearing bronze, containing about 15 per cent lead, and (2) piston packing-ring metal nominally 50-50 copper-lead. Part of both lots was kept for analysis. For heating, the alloys were contained in crucibles made by drilling a 1-inch hole in a cylinder of pure, solid graphite (round electrode). The surface of molten metal in this crucible would have an area of, say, 0.79 sq ins, because the surface tension produces a convex surface. The crucibles were charged into a furnace, and fired with gas and air already heated to a temperature of about 825°C. Temperature was measured with a Leeds and Northrup optical pyrometer.

The heat was gradually increased, care being taken to maintain a strongly reducing flame, until at the end of an hour the temperature was 1150°C, and the surfaces of the molten alloys were clean and mirror-like, practically all over. At the end of two hours the temperature was

about 1250°C and was then somewhat reduced. After another twenty minutes' heating, the crucibles were removed and quickly cooled by a jet of gas, preventing any but very slight surface oxidation of the alloys. The alloys were weighed and analysed, with the following results:

	Weight of alloy	Analysis*	Weight of lead
A 1 Journal Bearing	gram	per cent Pb	gram
Before	107.931	14.02	15.132
After	105.809	12.40	13.120
	2.122		2.012
A 2 Ring Metal			
Before	50.846	57.73	29.35
After	49.222	55.1	27.9
		58.8	
	1.624		1.45

The agreement in the results on the bearing bronze (A-1) is as close as could be expected, possibly a full analysis would explain the small discrepancy by showing a loss of zinc. In the case of the ring-metal (A-2) the agreement is not so good, because of the difficulty in getting a true sample of the alloy, which is very liable to segregation. Why the loss in this case is so much less than in case A-1 we cannot definitely explain. There would be more or less complete liquation as the alloy fused, resulting in a layer of lead below and a layer of copper above, the copper having no tin content (as most other bronzes have) dissolves very little lead, and with a lower lead concentration at the surface we have less volatilization.

Experiment B—A weighed amount of pure commercial lead was heated in an ordinary plumbago crucible (graphite-clay mixture) during the latter part of the furnace treatment described under experiment A. The charge was put in when the furnace was about 1200°C and was heated for forty minutes, then was cooled under a gas jet. An empty control crucible of the same kind was heated along with it, but was not needed, as the lead came out easily after heating. The results are as follows:

	Control Crucible	Charge	Loaded Crucible	Lead
	gram.	gram.	gram.	gram.
Before	81.448	162.224	86.458	75.766
After	80.274	159.649	85.055	74.534
Loss	1.174	2.575	1.403	1.232
		1.403		
Loss of lead		1.172		1.232

* Analysis by J. T. Donald & Co., Montreal, Que.

The exposed area of the lead in this case was 1.23 square inches. The loss is comparable with that in experiment A-1, which was in the furnace much longer, thus:

Disregarding temperature, which averaged higher for B than for A, and calculating the loss of lead per square inch per minute, we have,

	Loss Pb/sq. in./min
Bronze (A-1)	0.019 gram
Pure lead (B)	0.025 gram

This is a reasonable concordance, considering the temperature difference.

OBSERVATIONS IN A FOUNDRY

In order to apply the results of the preliminary laboratory experiments described above, observations were made in a representative bronze foundry during one afternoon's casting operations.

At the time, melting was being done in several gas-fired one-pot crucible furnaces. The gas flames escaped directly into the melting room, coloured green by copper, but there was no sign of lead smoke from this source. Normally in this foundry the large output of lead-carrying railway bearing bronze is melted in a completely closed electric arc furnace 1,000 pounds at a time. The gas furnace crucibles hold about 350 pounds each, two or more crucible melts are combined in a large ladle for large castings. The output of the foundry is from 10,000 to 15,000 pounds per day.

The crucibles of molten alloy as they come from the melting furnace are covered with dross produced from dirt and sand on scrap metal, oxide, etc., and fume very little. The dross is skimmed off and the alloy immediately produces a cloud of fume, or "smoke." In the case of "phosphor-bronze" the surface remains clean and continues to fume, apparently the oxygen at the surface of the metal selects the phosphorus (which is there for that purpose) and the fume probably consists largely of phosphorus pentoxide, but if the alloy contained any considerable amount of lead it would volatilize and go off as oxide also. Usually phosphor-bronzes are low in lead. On the other hand, non-phosphorous bronze (lead-carrying "acid resisting" bronze was observed on the day in question) seems over with a film of oxide very quickly after being skimmed, and

then fumes very little from the surface in the crucible, but copiously from the stream of alloy as it runs into the mould. High-zinc brasses fume very badly owing to the volatility of the zinc, and "ornamental yellow" brass may contain considerable lead, but "manganese bronze" (really high-zinc brass) is free from it. "Steam metal," containing 5 per cent each of tin, zinc and lead, we would expect to have intermediate properties.

Several observations were made of the time required to pour a crucible of alloy, including the time the stream of clean, fuming metal is actually running into the mould, and the total time a crucible is in hand. These times vary with the size of the castings being poured, and other factors, but average about three minutes and six minutes respectively.

In regard to the surface exposed we would estimate, say, twenty-five square inches for six minutes for the partly skimmed, slightly fuming surface in the crucible, and the equivalent of a cylinder three inches in circumference and eight inches long, say, another twenty-five square inches for three minutes for the stream running into the mould.

Using our figure 0.02 gm loss of lead per square inch per minute, we find that 4.5 gm of lead are discharged into the atmosphere of the casting room in the six minutes required to dispose of each 350 pounds of alloy. Assuming a room fifteen metres square and five metres high, and no circulation of fresh air, we have a concentration of four mgm of lead per cubic metre of air. There is, of course, a circulation of fresh air, but the draft is quite likely to carry the concentrated fumes directly toward one of the workmen handling the crucible.

PREVENTION

In order that we may formulate an intelligent program for the prevention of lead poisoning in foundries certain fundamental facts should be known.

1. What is the dangerous concentration of lead fume in the air?

2. How much lead can be absorbed daily by an average man with comparative safety?

3. What percentage of inhaled fume or dust is retained?

With regard to the first two questions our knowledge is admittedly inaccurate, for any

investigator is handicapped by the difficulty of getting human subjects to experiment upon, and experiments on animals cannot be considered strictly applicable to human beings. Legge^{4, 5} has estimated that with a concentration of 0.5 mgm of lead per cubic metre of air men will rarely develop colic and never encephalopathy. Teleky^{4, 5} believes that a daily dose of a little more than 1 mgm of lead over a period of several months will cause plumbism.

The third question as to what percentage of inhaled fume or dust is retained has recently been considered by Drinker, Thomson and Finn⁶. These authors, using human subjects, experimented with zinc oxide fume (particle size about 0.4 micron), zinc oxide powder, ["Kadox" (particle size about 0.15 micron)], and marble dust (particles varying from 0.3 to 6.0 microns). Then determinations were remarkably uniform. For the zinc oxide fume the percentage of dust retained averaged 57 (± 10.8), for the "Kadox" the percentage averaged 56 (± 7.3), and for the marble dust the percentage figure was 54 (± 9.2). The average percentage retention of the three was 55, with a probable error of ± 9 . We believe that these determinations are as accurate as it is possible to obtain, considering the rather marked variability in different subjects, but it is only fair to state that Lehmann, Saito, and Gföhrer⁷ in 1912 obtained a much higher percentage retention with white lead dust. However, since the experiments of Drinker *et al* were with fume and more nearly fit our present problem, we are inclined to accept their results.

If we assume, therefore, that approximately 50 per cent of inhaled dust and fume is retained, we find that the concentration figure of 0.5 mgm per cubic metre of Legge, and the dosage figure of 1 mgm. per day of Teleky, check rather well. If the tidal air of an average man is 500 cc and sixteen respirations are taken per minute, the amount of air inhaled by a man during eight hours is 384 cubic metres. At a concentration of 0.5 mgm per cubic metre 1.92 mgm of lead are inhaled and 0.96 retained, which corroborates Teleky's figure very well.

The prevention of lead poisoning in foundries, or anywhere else, for that matter, resolves itself into the problem of preventing the workmen from inhaling more than a toxic amount of

lead per day For the purpose of our calculations we have accepted the statement that 1 mgm of lead per day is the maximum dose allowable*

From the calculations given earlier it will be seen that when a crucible with a 350 pound charge of lead alloy is poured, probably 45 gm of lead are discharged into the atmosphere At the point of discharge the fumes are very concentrated and may be directly inhaled if they happen to blow toward the men doing the pouring When the fume has been distributed throughout a room of the size mentioned (1125 cubic metres) the concentration becomes 4 mgm of lead per cubic metre Through leakage this concentration will gradually become less and less until the time of the next pouring when a fresh charge of lead is introduced into the room, and the cycle starts again We have not had facilities for making actual determinations of the lead concentration in the air, and we doubt whether they would be of great value on account of the difficulty in obtaining representative samples We are assuming that the maximum concentration of lead in the room under consideration varies from 4 mgm per cubic metre to zero concentration, with an average concentration of 2 mgm per cubic metre That is, we are assuming that under the worst conditions (namely, in winter when the windows are closed) the men in the moulding room are constantly exposed to an atmosphere averaging 2 mgm of lead per cubic metre of air This, according to Legge, is at least four times the safe concentration Under these conditions the problem is to prevent the men from absorbing 1 mgm of lead per day

PROPHYLAXIS

Masks—In regard to masks it may be said at the outset that it is very difficult to get men to wear them for eight hours a day In the presence of dust and heat masks become very uncomfortable, and at best they should be looked upon as a last resort Furthermore, it is questionable whether the average commercial mask (such as the so-called pig-snout mask) is of much value in the presence of very fine fumes

Brown,⁸ in his study of lead poisoning among men working at the scrapping of naval vessels, where the lead in the paint is volatilized by the

oxy-acetylene torch, states that experimentally the Burrell modified industrial mask, with type GMC-1 canister, proved to be the most satisfactory of several masks tested The canister, which is connected to the mask by a flexible hose, contained four absorptive layers, soda-lime-charcoal, cotton, soda-lime, charcoal This mask appeared to retain the lead fume when tested in the laboratory, but "it failed to reduce the incidence of plumbism" Barreto, Drinker, Finn, and Thomson⁹ state that if the original Burrell dust mask is impregnated first with a fine fume like zinc oxide its efficiency becomes quite high The Burrell dust mask consists of a face-piece connected to the dust filter by a non-collapsible hose The filtering medium is large in area (approximately 840 square inches)

The Mines Safety Appliance Company's standard mask, type M-S-A, which depends on furnishing the man with pure air through a hose connection, might be expected to furnish good protection It would not be practicable to have men wear this type of mask with unwieldy hose connections at foundry work, however

It is our belief that it is not reasonable to require men to wear respirators all day long at their work, and that some other method of protection should be devised

Ventilation—It might be practicable to dilute the lead fumes to a safe concentration by the introduction of outside air As a matter of fact this is what appears to happen in summer, for there can be little doubt that the incidence of lead poisoning in bronze foundries is greatly reduced in summer when the windows are wide open

If we assume that 350 pounds of lead alloy are poured every hour, according to our calculations 45 gm of lead are discharged into the atmosphere at each pouring To dilute this to 0.5 mgm per cubic metre of air, 9,000 cubic metres of air per hour will be required This is equivalent to 5100 cubic feet of air per minute This is a high calculation since we have made no allowance for natural ventilation A properly designed fan of less than two horsepower could supply 5100 cubic feet of air per minute¹⁰ The running expenses would be chiefly in the heating of the air and should not be high, for the normal problem in a foundry is one of cooling

rather than heating. With a plenum system of ventilation the air should be delivered through multiple ducts in various parts of the room, but concentrated chiefly about the moulds. It should enter the room at about the head level. With the introduction of large quantities of air to a relatively small room, exhaust fans may be required. If the room is large, however, and the ceiling high with a monitor roof, the delivered air can find ready escape. In connection with the use of exhaust fans, there seems to be an impression among foremen and others that their installation in side walls or roofs solves the problem of ventilation. Such fans draw their air locally, they exert a negligible suction at a distance of more than ten feet, and to expect an ordinary exhaust fan to remove fumes from a moulding operation many feet away is unreasonable.

The furnaces should be equipped with hoods connected with exhaust fans. The degree of volatilization of lead is probably not high at the furnaces on account of the dross covering the molten metal, but doubtless some fumes escape and the problem of removing them at this point is not difficult. It may be practicable to remove the fumes over some of the moulds by local exhaust ducts, and in the foundry where most of our observations were made this has been done in the case of the piston packing-rings. In many moulding operations the use of local exhaust ducts is hardly practicable, for in order to make them effective they must be placed close to the moulds and this is likely to interfere with the movements of the moulders.

It is universal knowledge that certain individuals are much more susceptible to lead poisoning than others, and in the presence of relatively small amounts of lead will develop poisoning. To eliminate these, and to keep an accurate check on all the workmen, the men who are exposed to the risk of plumbism should be periodically inspected by a physician who is qualified to detect the early signs of the disease. Such an inspection should be carried on at least twice a month, and preferably weekly.

Milk should be furnished to the men. It is a time-honoured preventive of lead poisoning and there is a rational basis for its use.

We subscribe to the view that most of the lead is absorbed through inhalation rather than ingestion. Nevertheless other routes of absorption should not be neglected. To reduce the chances of swallowing lead, provision should be made for eating away from the moulding room, and facilities for washing should be provided. Smoking and chewing should be forbidden while at work.

SUMMARY

Ten cases of lead poisoning which we have seen recently are reported, not because they present anything of unusual interest from the clinical standpoint, but because they occurred among bronze foundries.

It is not universally known that bronze frequently contains lead, sometimes in large amounts, and that in the melting operation a very high temperature is reached, high enough to cause considerable volatilization.

We have determined the volatility of lead from bronze at the temperature at which it is treated for casting (2100°F), and find that it is in the neighbourhood of 0.020 grm per square inch of molten surface per minute.

Calculations are given as to how much lead is probably volatilized during the operation of pouring the metal into moulds, and suggestions are made as to how this lead fume may be removed or diluted, so as to reduce the hazard of plumbism, which is often very great.

WHAT IS A PÆDIATRIST?*

BY F. M. FRY, M.D.,

Montreal

DEFINITION—Originally a pædiatrist was one who with reasonably good mental equipment, had sacrificed his time and money in such prolonged study and experience in children's diseases that he could in all honesty offer to practise in that line only, and, by giving unusually complete and scientific examination with treatment to his patients, deserve an honest high reputation in the minds of his patients and of his confidèes as a genuine specialist in his chosen branch. Are these the qualifications of all or most men who are to-day crowding into the ranks of specialists, and are we doing our share to prevent the name of pædiatrist being debased as much as "professor" or even "doctor" or "specialist" have been in the past by unscrupulous people?

With haste and disregard of correct spelling, the overwhelming majority of us even in universities and hospitals are too utterly careless of scholarship to preserve the diphthong in "pædiatrics" as if we did not know that 'pæd' is a Greek root meaning 'child' and 'ped' is a Latin root meaning 'foot'. Hence one has been sincerely asked by laymen evidently better educated than we are if pædiatrists are not foot or corn specialists. With paradoxical action while the first syllable has been shortened the word has been lengthened with a love for long resounding words into pædiatristian with very doubtful gain.

Is Pædiatrics a Specialty?—This might be answered from the point of view of either (a) the faculty (b) the practitioner or (c) the patient.

(a) There are still those who hold that pædiatrics is merely a part of clinical medicine, calling for no division either in college or hospital. Such men are not interested in the diseases chiefly functional of young infants any more than they are keen to bother about the

heavy mortality of "summer diarrhoea", and yet they prevent competent, trained men doing so through academic channels. But this has been amply if tardily corrected by at least our large universities and need not detain us here except to confirm the claim that from the academic point of view, pædiatrics is a special branch certainly in regard to children up to about ten years of age.

(b) Practitioners have shown less delay in seeking consultants and have long recognized the specialty, not only as a means of sharing responsibility in moribund cases but also for the benefit of their patients even if as all specialists complain they do not seek our aid as early as we think they should.

(c) The patients at least the youngest and most liable to fatal disease cannot speak for themselves but of course it is the patients who should settle the question whether the community needs a specialist for sick children. It is safe to say to a pædiatrist audience that the last two decades have amply proved that the pædiatrist, even from economic and political points of view (e.g. in vital statistics) has emphatically won a position of value to the public.

If then we are dealing with a genuine specialty why notice the odd delinquent who would enter the ranks without tan preparation? All branches of activity have such black sheep. Only because the hard-won good name of pædiatrics has been gravely threatened by the increasing numbers of men who pose as pædiatrists and demand specialists' fees without honestly fitting themselves for their work by any tan amount of study or experience. In writing so one is not citing conditions only in one's own home city or province or country. Information comes chiefly from clear-headed general practitioners chatting at medical conventions or conditions all over Canada and in many parts of the United States. Many men go away to one hospital in one city only, for

* Read at the annual meeting of the Canadian Society for the Study of Diseases of Children at Vancouver June 29, 1928.

several months, others for weeks only (1) and return "specialists" though scandalous and dangerous men. Men have left another specialty to become pædiatrists over night, others, after being general practitioners, become "pædiatrists" with no special training whatever. One would not mention this, were not some such men at once welcomed in and appointed to universities and hospitals which thus countenance and encourage the untamed "specialists." Another source of information is the kind of treatment a consultant meets and which must result from hopelessly scant training.

The Remedy—One might be thought pharisaical in appointing himself a judge over his confrères, certainly, his writing would be utterly futile unless he had very practical suggestions as to the prevention or cure of this condition. While the motive of this little paper is to call attention to the present menace to the good name of pædiatrics, our only justification lies in making the following practical suggestions.

SUMMARY

1 The good name of pædiatrics is, to a very great extent, in the hands of those who appoint doctors to teaching posts in the universities, to clinical posts in hospitals, and who give permission to work in clinics.

2 Let us accept only those with at least good average ability. Men have gone away to study for a specialty, who from lack of ability, could never by any amount of study become real specialists.

3 Appoint those only who can and will study for a year or two in this line.

4 Favour those who have had several years' training in general medicine in hospital, or better, in several years' practice.

5 Insist on prolonged industrious study in at least three large pædiatric clinics.

6 Favour those who have studied in Europe as well as in America.

7 Heartily support and encourage those who will sacrifice time and money in so preparing themselves for respectable and honourable special practice.

The Influence of the Crusaders in Medicine—"Between the years 1095 and 1270 A.D., Europe was rocked by the militant Crusaders. Morbid religious faith, working upon a disturbed nervous system, caused people to have distorted views of life and made them fall an easy prey to the adventurers who stirred up crusading expeditions. The travelling crusaders represented all types of people and as they advanced by slow marches, begging food and clothing as they went, they spread disease in every community they came in contact with, and prepared the way for countless epidemics. The sickness promoted by the crusaders gave wide scope for the exercise of medical skill.

"Roger, King of Sicily, published an ordinance compelling physicians to be registered by the district magistrates, after suitable examinations, and the schools of Salerno and Naples were designated the only colleges for the instruction of qualified physicians. This ordinance appears to have been effective in improving the status of medical men, because we find such men as Albertus Magnus (1193-1280), Vincent de Beauvais (1221-1264), Hugo de St. Victor (1087-1140), Thomas Aquinas (1225-1274), and Roger Bacon (1214-1292) becoming active in medicine. These were all college-trained doctors and well-rounded scholars who did valiant work in uplifting medicine. We may

say, therefore, that the crusaders, while spreading serious epidemics of disease, and causing much sickness, turned public attention to the need of medical schools and better medical education. These benefits must be credited to them, as well as the establishment of hospitals, poorhouses, baths, and asylums throughout Europe."—*The Physician Throughout the Ages*, New York, Capeheart Brown Co.

Synthetic Substitute for Ephedrine—With the comparatively simple and inexpensive synthesis of phenylethanolamine sulphate by a new method, Hyman Miller and George Piness, say they have at hand a drug comparable pharmacologically to ephedrine but considerably less toxic. Clinical evidence points to the inactivity of phenylethanolamine sulphate on oral administration, and to an advantageously weak pressor but disappointingly weak bronchodilator effect on hypodermic injection. The field of the greatest usefulness of phenylethanolamine sulphate in therapeutics is apparently as a topical application in the nose, in which its activity is in every way comparable to that of ephedrine. The addition of a new drug to the already overcrowded pharmacopeia requires considerable justification. This justification, they believe, may well be found in the evidence here presented.—*J Am M Ass*, 1928, xc1, 1033.

Case Reports

PERNICIOUS VOMITING OF PREGNANCY, WITH AUTOPSY FINDINGS*

By S. KOBRINSKY, M.D.,

*Lecturer in Obstetrics, Faculty of Medicine,
University of Manitoba,*

Winnipeg

Mrs. A. G., French Canadian, Roman Catholic, aged 26, was admitted to St. Boniface Hospital on May 19, 1928, on account of persistent vomiting.

Family History—Her father, mother, nine sisters, and three brothers are alive and well. Two sisters died from pernicious vomiting of pregnancy, one at the age of 19, when her first pregnancy was advanced to 2½ months, the other at 26, in the third month of her fourth pregnancy.

Personal History—The past history was negative save for an attack of influenza in 1918, when she was ill one week. Menstruation began at 14. It was regular every twenty-eight days and lasted four to five days, not profuse nor accompanied by dysmenorrhœa. She was married in November, 1927, and her last menstrual period began March 9, 1928.

History of Illness—She felt fairly well until the end of April when she began to have pronounced nausea and vomiting, chiefly in the morning. This condition grew worse and was aggravated by severe headaches. From May 14th, she was unable to retain any food taken by mouth.

Physical Examination—A fairly well nourished young woman. The heart and lungs were negative. The fundus uteri could be palpated just above the symphysis. Blood pressure was 128-90. Urinalysis: albumen and sugar not present, acetone + + +, diacetic acid +, pus +.

The treatment consisted in absolute rest in bed, nutrient enemata, 500 c.c. of 10 per cent dextrose intravenously daily, with 20 units of insulin.

Some improvement was noted, and on May 24th the acetone and diacetic acid had dis-

appeared from the urine, but albumen, hyaline casts, red blood cells and bile were present. Theicterus index was 27, van den Bergh's reaction, immediate direct. Evacuation of the uterus was considered.

On May 26th Dr. Lennox Arthur saw the patient in consultation. Following this, evacuation of the uterus was advised but consent could not be obtained. In addition to the dextrose, 25 c.c. of 10 per cent magnesium sulphate was administered intravenously every two hours for two days, later, three times a day. Again there was apparent improvement and she was able to retain some fluids by mouth. On June 4th, the icterus index was 17, the urine, however, contained a trace of albumen, acetone and occasional casts. Three days later she grew much worse.

Urinalysis: acetone, a trace, diacetic and albumen, a faint trace, hyaline casts present. Blood urea nitrogen was 14 (normal). In spite of treatment she became comatose and died on June 13th.

An autopsy was performed by Dr. Jas. Piendeigast, pathologist to the hospital, on June 14th.

Post Mortem Findings—Lungs showed congestion of their bases with moderate œdema. The pericardial sac and heart were negative.

The peritoneal cavity was dry. The alimentary tract was distended with gas, but the serosa and mucosa showed no gross changes. The pancreas was negative. The spleen somewhat small but soft, the pulp a pale red. The gall bladder had a distended wall of normal thickness, but the lining showed a definite strawberry appearance, background was pale yellowish and green in colour, no calculi. The liver was rather small weighing 1380 gm., softer and more friable than normal, of a uniform very pale colour and of homogeneous texture, without any signs of hæmorrhage. Kidneys, left, 125 gm., right, 120 gm. Both were alike in appearance, quite congested, with smooth surface, the capsule stripped easily. Adrenals well developed and apparently normal. Ureters and bladder were negative.

* From the Department of Obstetrics, St. Boniface Hospital.

The uterus was the size of a large orange and soft. It contained an apparently healthy fetus (the history pointed to a three months' pregnancy).

Microscopical Examination—The predominating feature in the kidneys was the marked tubular changes, parenchymatous or cloudy swelling, the glomerular apparatus was intact. The appearances were those of the nephrosis of pregnancy.

The liver showed no microscopical hæmorrhages, no cellular infiltration. Cloudy swelling was present. There was also some fatty degeneration, but this process was by no means general. The gall bladder (strawberry), spleen, adrenals, pancreas, ovaries showed nothing peculiar.

SUMMARY

A fatal case of pernicious vomiting of pregnancy in an apparently healthy young woman.

Death of two sisters from the same cause.

Operation to evacuate the uterus refused because of religious convictions.

Apparent, though only temporary, improvement following administration of magnesium sulphate solution.

Autopsy findings by a skilled pathologist.

This opportunity is taken to thank Sister Moquin and Dr. Dwyer for their untiring efforts in this case.

A CASE OF RAT-BITE FEVER

By R. CAMERON STEWART, B.Sc. (ARTS), M.D.,
*Associate in Pædiatrics, Royal Victoria Hospital,
Montreal*

Rat-bite fever, as the name implies, is a generalized infection following the bite of a rat. The condition presents a picture so definite in its outlines, and responds so promptly and favourably to the proper therapeutic measures, that it is undoubtedly a clinical entity due to a particular infective agent. The disease is so distinctive in its later stages that it can then be easily differentiated from an ordinary septicæmia, the latter, which might result from a rat-bite as readily as from any other kind of bite, and may cause some diagnostic difficulties during the first few days of fever.

Rat-bite fever, also known as *Sodoku*, appears

to be more common in the Orient, and much of the best work on the subject has been done by Japanese investigators. The disease was first described in detail by Miyake in 1900. Treatment with Salvarsan was introduced by Hata about 1912. This type of arsenical therapy has proved so uniformly successful that it still remains the one of choice.

The disease has several major characteristics, among which are

1 The preliminary bite of a rat or of some animal, as a cat or a ferret, which has been in contact with rats.

2 An incubation period of ten to thirty days or more, usually about two weeks.

3 A temperature curve which runs a typical course. It is suggestive of malaria or relapsing fever, the paroxysms recurring at regular intervals of several days, the temperature rising gradually to a maximum on the second or third day and falling by crisis, often accompanied by sweating. During these periods of fever there may be headache, muscular pains, dysphagia, thirst, nausea and vomiting. The leucocyte count rises, reaching 15,000 or more.

4 Skin reactions, of several forms,

(a) Reaction at the site of injury—redness, tenderness, and swelling, in other words, an erythema. The outlines are well defined, the edges slightly raised and of somewhat deeper colour, there is no tendency to abscess formation.

(b) A similar reaction over the proximal lymph-nodes, which may become palpable.

(c) An erythema about the neighbouring joint, when the bite is on an extremity.

(d) A general macular eruption over the body and extremities, consisting of circular reddish spots, from one to three or more centimetres in diameter, slightly elevated, with sharply defined edges. These spots tend to disappear on pressure and do not itch or desquamate. After one or two of the paroxysms of fever the spots may become somewhat ring-shaped, resembling the lesions of erythema multiforme.

During the remissions of temperature the local erythemas and macular spots fade but do not disappear.

5 Rapid response to treatment with Salvarsan or similar arsenical preparation. One injection usually effects a cure.

If untreated, the duration of the disease is indefinite. The mortality is said to be about 10 per cent.

The marked periodicity, so similar to that exhibited by relapsing fever, the prompt response to arsenical treatment, and the positive Wassermann reaction that can sometimes be demonstrated, all suggest that the condition is one of spirochætal infection. These organisms have been found in the blood in so many human cases that they are accepted as being the causative agents. The particular variety involved is called *Spirochæta morsu muris*. It would seem that rats and similar animals are somewhat prone to infection with spirochætes and often harbour these organisms without obvious signs of disease.

The following are details of a case which last year came under observation.

An infant of seven months, previously healthy and with irrelevant personal and family history, had the left cheek bitten and the upper eyelid scratched presumably by a rat. Some redness and swelling followed and the baby was taken to the Out-Patient Department of a hospital, where hot boracic fomentations were advised. The condition improved within the next few days and the child appeared practically well. Thirteen days after the injury the lid again became swollen and red. Three days later the patient was admitted to the Royal Victoria Hospital. There was persistent fever and the swelling of the lid caused the eye to become closed. The swollen lid was later incised, but no pus was obtained.

Twenty-five days after the initial bite a macular eruption was noticed. The temperature became definitely relapsing in type, the skin

lesions brightening and fading with its rise and fall. These lesions were of the typical character already described: a circular area of erythema with well defined edges, surrounding the inflamed and swollen eyelid, another area in front of the left ear, over the lymph node, macules about twenty-five in number, distributed over the face, trunk, and extremities. During the periods of fever the child cried a little and appeared to dislike being handled, probably an indication of malaise. The general condition remained good in spite of the high temperatures registered during the exacerbations, there seemed to be no acute pain, and nourishment was well taken.

There was a moderate leucocytosis counts varying from 10,200 to 18,600. The urine was negative. Old tuberculin 1/10 mgm intradermally gave a negative reaction.

The Wassermann test on the blood was negative.

Several attempts to demonstrate the spirochæte were unsuccessful.

As there seemed little doubt in regard to the diagnosis and it was deemed inadvisable to delay treatment too long, sulpharsphenamine was given on the thirty-sixth day after the injury with rather dramatic results. The injection (indicated on the chart by the first arrow) was made at the height of an exacerbation, 70 mgm being given intramuscularly. The weight of the baby was 7 kilos (16 lbs).

The temperature thereafter remained practically normal, the skin reactions rapidly disappeared and the eye opened with the subsidence of the swelling of the lid. As a precautionary measure a second dose of sulpharsphenamine (105 mgm) was given eight days

CHART I

Rat bite fever showing course of temperature before and after treatment

after the first (second arrow) The child was discharged from hospital a week later, apparently well There has been no return of any symptoms suggestive of the condition.

This case, from the records of the Department of Medicine, Royal Victoria Hospital, is presented as one of comparative rarity on this continent, though sporadic instances of the disease are reported from time to time The infection has been used, like malaria, to some extent in the treatment of neuro-syphilis

Acknowledgement and thanks are due to the Departments of Ophthalmology and Bacteriology of the hospital for their co operation, and to Dr H. B. Cushing, Professor of Pædiatrics, McGill University, and Physician to the Royal Victoria Hospital, for invaluable aid.

A CASE OF EARLY PREMATURE LABOUR WITH SURVIVAL OF THE BABY

By WILLIAM J. STEVENS, M.D., C.M.

Attending Obstetrician, Ottawa Civic Hospital

Ottawa

The survival of premature infants under the usual period of viability is sufficiently rare as to warrant reporting this case

The mother was a primipara, 27 years of age Her statements are considered authentic and reliable

The patient had had four months' antenatal care Her history was irrelevant, except that her menses had always been somewhat irregular She suffered moderately from morning sickness Her pelvic measurements were normal, also the urine and blood pressure

On the night of March 31, 1928, the patient went into labour without any apparent cause and was taken to hospital She was given rectal synergistic analgesia with good success and was delivered normally at 8.25 p.m. of a female baby weighing 3 lbs and measuring 36 centimetres long Wassermann tests were negative The baby appeared to be quite premature and weak Everything was done to save the child, and its survival, on account of the duration of the pregnancy, becomes the chief point of interest

The patient's last period was August 1, 1927, she was married on September 7, 1927, her delivery occurred on March 31, 1928, making the birth approximately 204 days after marriage, or about 6½ months

After delivery, the baby was oiled, rolled in a cotton jacket, and treated in a special compartment for premature babies Its temperature was maintained by means of a hot water bottle, and the room was kept at 85° and the humidity between 50 and 60° Gauze diapers were used and the baby practically left unhandled The baby was given 5 per cent lactose solution, one drachm every two hours with a medicine dropper On April 2, the mother's breast milk, diluted with equal parts of 5 per cent lactose, was given (four drachms by gavage every three hours) The evident need of fluids was shown, and on the fourth day the baby received 30 c.c. of normal saline intraperitoneally Further intraperitoneal injections were given on the 5th, 7th, 8th, 10th, 12th, 15th, 17th, 19th, 20th, 21st, 22nd and 23rd of April On April 16th the baby was put on a formula by gavage of butter soup, breast milk not being available Later on lactic acid milk was used, then protein milk with cod liver oil by gavage and later by Brecht's method The temperature varied from 98° on March 31st to 99.4°, with the exception of 103.4° on April 17th, when daily intraperitoneal feedings seemed to substantiate the apparent lack of fluids The weight of baby, 3 lbs at birth on March 31st, fluctuated between 2 lbs 10 ozs on April 2nd, 2.8 on April 12th, 2.10 on April 15th, 2.12 on May 1st, 2.15 on May 10th, 3 lbs 3 ozs on May 12th, 3.9 on May 25th, 3.11 on May 30th, 3.15 on June 7th, 4.2 on June 14th, and 4 lbs 6 ozs on June 21st, the date of baby's leaving the hospital on the mother's insistence, the eighty-second day of its age

Since discharge from the hospital the baby has received good average maternal care at home and the protein milk formula has been continued On September 14, 1928, the baby weighed 8 lbs 14 ozs, on September 21, 1928, its weight was 9 lbs 1 oz and it is doing very well

We have had no other case as premature as this one in which success has attended the raising of the baby

Retrospect

THE PRESENT STATUS OF THE TREATMENT OF VARICOSE VEINS BY INJECTION

By L. H. McKim, M.D.

Montreal

Although the pioneer work on which this method of treatment is based dates back to 1851, when Pravaz injected ferrie chloride in the treatment of aneurysm, very little was heard of it, the procedure being regarded by the majority of surgeons as a much too dangerous method, on account of the possibility of embolism. During the past two years, however, many different workers having reported successful results, it is felt that a brief review of the general consensus of opinion at the present time may be of interest.

Gay, in his book on Varicose Disease, published in 1868, mentions the application of the ferrie chloride injection treatment of Pravaz to the treatment of varicose veins, and refers to its use in England, France, and Germany at that time. The bulk of the credit for the development of the method in recent years seems to be due to French workers. Tavel, in 1904, was apparently one of the first to use the method. More recently, Sicard and Gaugier¹, Genevri², Forestier³, Delater⁴, and Troisier⁵, may be mentioned as important contributors to the subject. Linser⁶, in Germany in 1912 and also in 1925, reported work along the same line.

Recent articles by three workers may be taken as summarizing the general trend of English, French, and American opinion at the present time. The authors of these are Douthwaite⁷, Forestier³, and McPheeters⁸.

Douthwaite's work is based on a series of more than one thousand injections since his first published work in 1926. He has given more than two thousand injections, using neutral hydrochloride of quinine,* and a smaller number, using sodium salicylate and also glucose. He uses only 1 c.c. at the first injection. If no idiosyncrasy for quinine is present he uses a considerably larger quantity on the next occasion. Injections are given at intervals of about one week. He occasionally uses perivenous injections in severe cases. He claims that intravenous injections are usually painless and that recurrences do not take place.

He also states that sodium salicylate is more painful, and more liable to cause sloughing, if any of the solution escapes into the tissues. He quotes Meisen of Copenhagen as reporting several cases of ascending phlebitis when using this substance. He has not personally used

bimodide of mercury. He has used glucose but has not had satisfactory results with it. Phenol and iodine solutions are not recommended by him.

Douthwaite claims that the obliteration is due to the irritation of the endothelium of the veins, producing an instantaneous phlebitis, limited in extent, and followed by the deposition of fibrin, and later organization. He claims that no accidents are recorded as following the quinine-urethane solution. He gives the following definite contraindications as to the use of sclerosing injections: (1) pregnancy particularly in using quinine, (2) old-standing or recent phlebitis in deeper veins, (3) diseases of the heart, with signs of imperfect compensation.

Forestier reports more than four thousand injections. He has used mainly three solutions: (a) sodium salicylate in 20, 30 and 40 per cent strength; (b) red mercuric iodide; (c) quinine hydrochloride and urethane.

He claims that no fatal cases of pulmonary embolism have followed the use of any of these solutions, but states that two fatal cases have been reported following the use of concentrated solutions of sodium chloride or glucose. He admits the occasional occurrence of colitis with diarrhoea and hæmorrhage after the use of mercuric iodide. He has never had a case of sloughing following the use of sodium salicylate. He emphasizes, however, the importance of not allowing any solution to escape into the tissues. He mentions the following as contraindications: (1) old persons with enfeebled health, (2) extensive œdema of the lower limbs, (3) recent attacks of varicose phlebitis, as he thinks there is a liability to rekindle the infective process in the latter, (4) varices accompanying pregnancy, which, he thinks, are due not to pelvic pressure but to endocrine disturbance, (5) collateral varices at the junction of the limbs and trunk, where the flow is proximal rather than distal, as in the ordinary varicose vein.

McPheeters' work is based on a series of 180 injections in 31 cases. He claims that 20 per cent sodium chloride is superior to all other solutions. The use of novocaine solution to prevent pain is dangerous on account of the danger of shock when administered by the intravenous route. He condemns the use of mercuric iodide as dangerous. Glucose is objected to on the ground of its viscosity, necessitating the use of too large a needle, with increased danger of leakage into the tissues through the point of entry into the vein.

The efficiency of sodium salicylate he considers as great as that of any other solution. The sloughing reported following its use he considers as due to improper technique in injecting, and its toxic effects as due to idiosyncrasy of the patient.

* Quinine Hydrochloride (B.P.) 40 grm
Urethane 20 grm
Aq. Dest 30 c.c.

which can be guarded against by proper testing out, as with quinine

Various other solutions are referred to briefly. The technique of injection is strongly emphasized, the chief points being the necessity of being certain that the vein has been entered before injection, and the prevention of leakage from the vein into the tissues after withdrawal of the needle. Two fatal cases are reported, one from fat embolism and the second from mercurial poisoning. Apparently these are not the same cases that are referred to by Forestier.

In a later paper McPheeters⁹ claims that the injection treatment can be started at once in badly infected ulcers. He reports the use of salt solution for extensive cases, also of calchrose, sodium salicylate, and mercuric iodide in resistant cases.

In a still more recent paper, McPheeters and Rice¹⁰ have collected a series of cases illustrative of various untoward results. They report having found only seven deaths which can be attributed to the injection method, as having occurred in about 53,000 cases. Of these, four were from pulmonary embolism. Sodium chloride was used in two of these cases, in one of which invert sugar was used in the other leg at the same time. Pregl's solution was used in one case, and the solution employed in the fourth is not mentioned, nor is the date of death, which in the first three cases occurred on the 10th, 14th and 23rd days.

Of the other three fatal cases, one died from "septic thrombo-phlebitis." Another died on the 29th day from septicæmia, after the excision of a piece of gangrenous skin on the 7th day, with subsequent infection. While this death is definitely attributed to septicæmia the patient had complained of pain in the chest. No autopsy could be obtained. The third case died on the 12th day from mercurial poisoning; he had received two separate injections of 1 c.c. of 1 per cent mercuric iodide.

Three other deaths from pulmonary embolism are reported, although the evidence is not so conclusive as in the four mentioned above. One of these was treated with glucose. Six weeks later he was operated on for hæmorrhoids with an infected anal fissure. He died on the 5th day after operation. The second case died one month after the injection of sodium chloride. He had thrombosed hæmorrhoids and the embolus was attributed to these. The third case died one month after treatment with glucose. Sloughing of a superficial knot of veins occurred. These were excised, and the patient died ten days later from pulmonary embolism. One non-fatal case of embolism is reported.

ANALYSIS

An analysis of the cases reviewed by McPheeters and Rice would seem to indicate the following conclusions:

(1) Seven deaths are attributable to the injection treatment.

(2) Three additional deaths following the treatment were probably due to other causes.

(3) Eight cases of pulmonary embolism have occurred after the treatment. Of these (a) four cases were attributable to the treatment, (b) one was attributable to the treatment but was not fatal, (c) three cases were fatal, but were probably not caused by the injection treatment itself.

(4) There were two cases of infection which proved fatal, one with septic thrombo-phlebitis, and one from septicæmia.

(5) One died from mercurial poisoning.

These authors think that solutions for injection may be arranged in their order of effectiveness as follows: (1) mercuric chloride, (2) sodium chloride, (3) sodium salicylate, (4) invert sugar solution, (5) metaphen.

Their choice for every-day use is, however, in the following order, sodium chloride, invert sugar, sodium salicylate, mercury, metaphen.

They consider that injury and stimulation of the vein wall is the object of injection, and that solutions which are coagulants of the blood should not be used. They believe that all extensions of the thrombotic or sclerosing process which occur following injections are due to secondary infective phlebitis, and that the presence of a phlebitis is an absolute contraindication for injection. They emphasize the importance of a careful technique and a knowledge of possible complications.

TECHNIQUE

T. H. Treves Barber¹¹ gives the technique in detail. He emphasizes the following points: (1) Begin at the lowest point, (2) Use small, sharp needles, (3) Be sure that the needle is in the vein, (4) Inject towards the trunk, (5) Have the patient lying down as soon as it is certain that the vein is entered, (6) Stop the injection immediately if any stinging or burning pain occurs or if there is any swelling over the vein, (7) Apply pressure over the puncture in the vein to prevent leakage.

Barber uses 15 per cent sodium chloride exclusively. He injects 5 c.c. of sterile water if he suspects any leakage of the salt solution into the tissues.

CONCLUSIONS

1. The treatment of varicose veins by injection must now be regarded as a surgical procedure worthy of consideration in cases presenting no contraindications.

2. Treatment by this method does not as a rule necessitate hospitalization.

3. Treatment by this method, while sometimes uncomfortable, is not as a rule unusually painful, when careful technique is observed and proper solutions are used.

4. Immediately painful results, as well as later sloughing of the skin and constitutional disturbances, are probably most often due to (a) faulty technique, (b) use of too large an amount of solution, (c) improper choice of

solution, (d) idiosyncrasy of the patient to the solution used

5 Seven deaths, including four cases of pulmonary embolism, are reported in approximately 53,000 cases

6 Recent phlebitis is an absolute contra-indication

7 Excision of a gangrenous slough should not be considered lightly, and if the slough is infected it is an absolute contra-indication

8 Absolutely no operative interference with an infected ulcer is permissible during the treatment

Association Notes

Re COLLECTION OF THE ANNUAL FEE

The following letter is being sent to all our members and calls for special attention

Dear Doctor,

During the past several years, the Association has received many suggestions from members living in various parts of Canada that our annual fee for the ensuing year be collected in the autumn rather than in the month of January

There are so many financial obligations falling due at the beginning of the New Year that medical collections in many parts of Canada are poorest at that time, and, conversely, money is more plentiful in the autumn and collections easier. Particularly is this said to be so in Western Canada. Moreover the early collection of the fee will eliminate the financial loss which is incurred in supplying *Journals* for a period of several months to members whose fees are in arrears

After very careful consideration at our last annual meeting, Council decided that the fee for the next calendar year should be collected during the months of October, November and December

We hope that all members of the Association will heartily concur in the change, and that the fee notices, when issued, will receive prompt attention

Yours faithfully,

(Signed) T C ROUTLEY,

General Secretary

Editorial

SLEEP

SLEEP, "the twin brother of death," is a natural phenomenon familiar to all. It is taken for granted, and, for that reason, probably arouses a very languid interest among the generality of people. Its opposite, insomnia, does have the effect of stimulating enquiry, however, and persons afflicted with this distressing trouble frequently consult the medical man, who, unfortunately, in regard to the physiological and pathological problems involved, is apt to be as ignorant as they are. For, strange as it may seem, the physiological state that we call sleep constitutes a problem by no means fully solved. The reason for this is that the subject has not attracted the attention it deserves, no great amount of experimental investigation has been carried out, what exists has been published at rather wide intervals, and has been inconclusive, not to say contradictory. The earlier work, that of Manacine¹ and Tarchanov² was done on puppies, and was followed by that of Sidis³ and Kleitmann⁴ with Lee⁵. Pieron⁶ and Pavloff used dogs. Bast, Loevenhart *et al*⁷ employed rabbits. The use of animals of different species and ages and of different methods to maintain the state of wakefulness makes it difficult to compare and accurately appraise the results.

The sleeping state is characterized by a number of familiar features which need only be mentioned to be admitted. The chief of these is the abolition of consciousness, and in this sleep resembles some other important conditions, such as, stupor, coma, catatonia and catalepsy, and syncope. Stupor and coma are conditions in which the patient can be brought back to consciousness partially and with difficulty, or not at all, waking from sleep is rapid and complete. In contradistinction to catatonia and catalepsy the muscles during sleep are in a flaccid state and the body responds quickly to stimuli. Syncope may be differentiated by its suddenness of onset, its fleeting nature, and the special circulatory phenomena.

But, besides the loss of consciousness in sleep, we have to note other features, the regular breathing, the quiet steady pulse, and the profound muscular relaxation. Under normal conditions a person goes to sleep fairly quickly, wakes up promptly after a sufficiency of rest, and during the sleeping period exhibits varying grades of response to external stimuli, depending on the character and intensity of those stimuli and the depth of the unconsciousness. At the same time certain of the bodily functions may be carried on, but on a lower plane of activity.

As all know, there are certain conditions that conduce to natural sleep, such as an accustomed hour, darkness, a well-ventilated room, a good bed, and *quietness*. Over-tiredness, mental activity, worry, an unsuitable posture, are all inhibitory. Sleep exemplifies very well the great law of periodicity as well as the law of habit. We go to bed at a certain hour every night, under favourable conditions, and with the definite intention of going to sleep. The oftener the attempt is made the easier is the end accomplished, so that in time a habit and a periodicity are established. Under the most favourable conditions sleep becomes automatic and inevitable.

Sleep has been interpreted in various ways. Rather fancifully, it has been held to connote a wish to return to the mother's womb, because the curled-up position of the normal sleeper resembles the fetal attitude. Actually, the flexion of the joints and the relaxation of the muscles are assumed because the position is the most restful, the least aggressive, so to speak, and may be seen in melancholics as well as sleepers. It is, appropriately, a negative rather than a positive thing, passive rather than active.

Sleep has been called a "death-wish." This view will not apply to the majority of people, it is certain.

It is an instinct, like the instinct that leads birds in the autumn to leave for warmer

climes As such, it can hardly be explained, unless on the basis of anticipation

It is a conditioned reflex, this on the authority of the great physiologist Pavloff Some words of explanation are required here

If food is shown to a hungry dog, immediately there is an outpouring of saliva This is a direct, or unconditioned, reflex But, if at the same time that the animal is fed a bell of a certain note is sounded the same result is obtained If this is repeated until an association of ideas is formed saliva will be secreted by the dog every time that particular bell is rung, even if food is not presented This is the conditioned reflex Pavloff found (1910-12) that, in the course of his investigations, it was difficult to keep the animals awake If the period between the action of the conditioning reflex and the giving of food was lengthened, the dog, concentrating his attention on the next event, would go to sleep, even if very hungry Furthermore, the constant recurrence of the conditioning stimulus, without food, would provoke sleep Pavloff assumes that the focussing of an excitation, in the case of natural sleep coming from the skin, on one area (motor) of the cerebral cortex causes inhibition of other areas Sleep, then, differs from other conditioned reflexes only in that there is a more extensive inhibition, affecting the whole cerebral cortex and even the sub-cortical centres There are, however, some observations that seem to indicate that this is not a sufficient explanation The development of conditioned reflexes requires the integrity of the cortex Yet, in decorticated animals more or less typical rhythmic sleep will occur The mechanism of sleep, then, is not entirely cortical, and does not depend altogether on generalized cortical inhibition

It is an auto-intoxication There is some experimental evidence in favour of this view For example, if an animal be kept awake a prolonged period its blood or cerebrospinal fluid, if injected into a second rested animal, will produce drowsiness in the recipient even if muscular fatigue and exhaustion are not operative in the donor The state of wakefulness, then, seems to lead to the formation of a toxin, which is different from the toxin of fatigue What this toxin is not known Examinations of the blood

during sleep have not revealed anything that seems of moment, except, possibly, that the concentration of calcium and potassium is lowered Much more evidence will have to be presented before this view can be accepted

Sufficient has been said to show that the problem of sleep is by no means a simple one Experimental investigation of the subject is fraught with special difficulties The only way to keep the experimental animals awake is by some form of muscular exercise Kleitman^s, one of the most recent workers, emphasizes that it is impossible to divorce experimental insomnia from muscular activity, and, for this reason, admits that his own results are of doubtful value And so are most of the other researches

One of the most plausible and widely accepted theories is that sleep is due to anæmia of the cerebral cortex One of the points in favour of this view is that we frequently become sleepy after a heavy meal (derivation of the blood to the alimentary tract) and that it is difficult for most people to sleep with the head low There is also the analogy between the unconsciousness of syncope and that of sleep Tarchanov (*loc cit*) found that the position of the head relative to the body was an important factor in inducing or preventing sleep in puppies Some puppies fell asleep more easily when the head was elevated above the general level of the body When the head was down it was impossible to make the animals fall asleep He also exposed the brain in his animals and noticed its condition both in the waking state and during sleep During sleep the brain is seen to be

at our last annual meeting, Council calendar year should be collected during November and December

of the Association will heartily concur in notices, when issued, will receive prompt

Yours faithfully,

General Secretary

of the red blood corpuscles, sometimes a fall in the temperature of 4° to 5°C towards the end, and death in convulsions. In the fatal cases Manaceine, followed by Pieron, and by Bast, Loevenhart and their associates, have described definite changes in the cells of the central nervous system, but such were not observed by Kleitman, nor do those mentioned quite agree as to the distribution of these lesions. It is notoriously difficult, for reasons connected with technique, to be certain that structural changes that may be noted in the cells of the central nervous system are actual and of import and not merely artefacts. If the changes described are really degenerative this would point to a toxic element in insomnia.

One phenomenon seems to be quite definite, and that is, that during sleep the muscles become markedly relaxed, returning to tonus so soon as the animal awakes. Kleitman's experiments in putting puppies to sleep confirm those of Sidis. The latter found that there was a tendency for the animals to fall asleep when they were placed under conditions in which they could relax their musculature. Sidis emphasized also monotony and limitation of movement, but it is possible that these factors are only contributory, in that they tend to promote greater muscular relaxation. Kleitman concludes from the evidence available "that sleep comes from a decrease in the number of afferent impulses reaching the central nervous system from the sensorium, and that muscular relaxation, decreasing considerably the

number of proprioceptive impulses, constitutes the last stage of the process by which sleep is precipitated."

This, perhaps, does not get us much farther, except that surplus connotations are eliminated. It seems clear that sleep is a necessary factor in the maintenance of life, but it is also an interesting speculation to enquire how it originally came about. Perhaps primitive man, tired with the chase or warfare, sat down to rest. For security's sake he would choose a retired spot or a dark cave. The approach of night, quietness, and muscular relaxation, all contributed to the feeling of comfort. The toxin of fatigue would produce a numbing of the sensibilities, and a loss of consciousness. The oftener this was done, the easier would be the inducement of sleep, until the process became automatic and periodical. Eventually, the toxic element, in many instances at least, would pass into the background, and the element of suggestion would become more prominent. May it not be that sleep is, in the main, a matter of auto-suggestion?

NOISE

number of familiar features will be mentioned to be admitted. The one of these is the abolition of consciousness, and in this sleep resembles some other important conditions, such as, stupor, coma, catatonia and catalepsy, and syncope. Stupor and coma are conditions in which the patient can be brought back to consciousness partially and with difficulty, or not at all, waking from sleep is rapid and complete. In contradistinction to catatonia and catalepsy the muscles during sleep are in a flaccid state and the body responds quickly to stimuli. Syncope may be differentiated by its suddenness of onset, its fleeting nature, and the special circulatory phenomena

inevitable, and, for the majority of people, inescapable. In some sense it is a measure of our progress in civilization, it is also to some extent an indication of thoughtlessness or callousness. If one stands on the summit of Mount Royal, overlooking the city of Montreal, he is conscious of a steady rumble above the muffled roar of a mighty sea. The quality of this noise will vary somewhat at different times of the day, but most of it is due to automobiles, lorries, tram-cars, trains and other wheeled vehicles. There is an occasional flavour of bells, whistles, and sirens. The latest enormity is the gramophone

phone which belches its cacophony over the sidewalk. Fortunately its range is more limited. Bells, on account of their ancient and hallowed associations, are probably not distasteful to many people. We have the poet's authority that they are musical, and music, according to Samuel Johnson, is "the most bearable of all noises." The most insistent noises are those associated with tram-cars and motor vehicles, as most persistent. "Flat wheels," squeaky brakes, and squawky horns provoke many a shudder.

We may properly enquire how far noise is inimical to health. That it is so, under certain circumstances, is tacitly admitted when we put up signs on our streets—"Hospital Zone Quiet Please." Incidentally, it may be remarked in passing that the modern hospital, with its steel and concrete construction, is not the quietest place in the world. It is really a vast resonance chamber. Metal doors groan and bang, footfalls and voices re-echo along the corridors, telephones are continually ringing, and conversation can be heard through the partition walls. This should not be. Certainly, noise interferes with sleep, far more than we are apt to realize, and lack of sleep is injurious. In this jazz age, with its high pressure performances both at work and play, its scandalous hours, and dietetic extravagances there can be little doubt that the nervous system is being maltreated. Add to this the influence of continual noise and in time "frayed nerves" will become general. It will be interesting to see what the effect of all this will be in the future on the production of psychoses and insanity. It is fortunate that there is a counterpoise to the insult of noise. When a stimulus is continuous or frequently repeated the recipient nervous mechanism becomes callous, it does not "register." This may be illustrated by the common experience with the clock. So long as a clock is going we do not hear it, but, if it stops we immediately become conscious of the fact. We have here a protective mechanism. Still, it may be doubted whether this protection is adequate. Influences that we are unaware of may yet be harmful, given sufficient time for their operation. Continual dropping wears away a stone. While it is difficult to advance concrete proofs on the matter there is little doubt in

the minds of medical men that the constant concentrated noise of our big cities is harmful. Authorities on nervous diseases have expressed themselves in this sense, notably, Sir Robert Armstrong-Jones.

What can be done about it? The measures, to be adopted will, naturally, vary in different places, according to local conditions. In Great Britain the profession through its great organ, the British Medical Association, has taken the first steps to bring about an improvement in the state of affairs. At the Annual Representative Meeting of the Association held at Cardiff a resolution was adopted calling for measures to be taken for the suppression of unnecessary noise in the interests of public health. The Medico-Political Committee, at a recent meeting, decided to take prompt action in pursuance of the resolution referred to. The Ministry of Health has been asked to receive a deputation and local branches of the Association will be urged to approach their local authorities both to make use of existing powers to deal with the nuisance and, when necessary, to apply for new ones. A conference has already been held at the Home Office between the Secretary of State, the Minister of Transport, and the heads of both departments. One of their conclusions is that "the increase in the volume of noise is largely due to the increase of motors, and of the uses to which motors are put, and to the abuse of various types of horns." It has been decided to draft regulations directed to abating the nuisance of motor traffic noise. Paris, which a few years ago, in certain thoroughfares, with its ramshackle cars, its cobble stones, and the incessant tooting of horns, was little short of an inferno, has taken recently a great step in advance. Motor horns may not now be used there between certain hours of the night. Other places might well follow their example. It is to be remembered, also, that noise is only one part of the question. Vibration, which is chiefly caused by trams and heavy drays, also enters into it.

When all is said, it would seem that the most important single factor is *speed*. Excessive speed increases the grind of the machinery, and the amount of vibration, necessitates the more frequent application of the brakes, and leads to greater blowing

of the horn And, it is just this factor of speed that is notoriously the most difficult to control To effect the necessary reforms

will require the active interference and co-operation of automobile associations and municipalities
A.G.N

PROGRESS IN MEDICINE

WE not only pride ourselves upon living in the most progressive period of the world's history, but sometimes are inclined to be boastful of this our good fortune

Few will take exception to the claim that science in general, and medicine in particular, has made as much progress during the last fifty years as during the whole previous history of mankind Some of our more enthusiastic members claim that the major part of medical progress has been made within the last quarter of a century It may be that even the latter assertion is within the range of fact

We are perhaps too much inclined to forget that active advance in medicine did not begin until within comparatively recent years We, of course, do not imply that great credit is not due to Hippocrates and others of the old Greeks who untrammelled medicine from the traditions and superstitions of the pagan priesthood, and who made it clear that there are no supernatural causes of disease Even after giving due credit to the old masters and to such schools as those at Alexandria and Salernum, and to the part played by Arabian physicians in the preservation of Greek teaching and the addition of a few new drugs, we are compelled to admit that medicine remained in a practically stagnant condition until Vesalius gave to the world the important facts about the anatomy of the human body It may help our orientation by remembering that this demonstration did not take place until some time after the discovery of America, which is not a remote date in history Nevertheless, except for the contemporaneous brilliancy of Paré in surgery, and the unique eccentricities of Paracelsus in general medicine, we can attribute little progress even to this period Enterprising Europeans had been exchanging glass beads or equally valueless trinkets for the valuable silver and gold ornaments of the original inhabitants of this Western hemisphere for nearly half a century before Vesalius began to attract

medical students to his classes at Padua, and Linacre, perhaps the greatest of medical humanists, to herald the revival of learning in England The stimulus of Vesalius, great though it was, was not sufficient to create that spirit of investigation which alone could establish medicine on a firm foundation Not until Harvey set forth his views on the circulation and supported them with his well-considered experiments did medicine really enter upon the path that led to progress The discovery of the circulation was the most momentous event in the history of medicine Harvey's methods at once excited the admiration of many, and with his work we may say the experimental method in medicine really began This was in the year 1628

Harvey and Malpighi proved the circulation to be a physical process, but threw no light upon the chemical processes, which even then were considered to be of very great importance It was really not until the eighteenth century was well advanced that scientists acquired definite knowledge about oxygen, nitrogen, and carbon dioxide, and that the understanding of respiration became possible

These discoveries in chemistry were made during the "Hunterian period," and this year marks the bicentenary of John Hunter's birth Hunter's contributions to medicine are very generally known, and we speak of him still as one of the three greatest surgeons of all time It is difficult, however, for us to realize that it is only a century and a half since John Hunter was recognized as a man of unusual qualities During the span of his lifetime, nevertheless, many most notable advances were made in medicine and the allied sciences The list of his prominent contemporaries in various fields of activity is a long one Sir Isaac Newton died only in the year preceding John Hunter's birth Linnæus and Boerhaave died when he was but a lad During the active years of his life, Albrecht von Haller, Stephen Hales,

Luigi Galvani, Giovanni Morgagni and Huxham investigated the problems of physiology, Lavoisier and Priestley developed our knowledge of chemistry, and Lettsom, Smellie, Mead, Cullen, Haygarth, Cheselden and Jenner were advancing our knowledge of clinical medicine

When we realize that these notable physicians and investigators lived within such a

short period of our own era we are impressed with the fact that little advance was made in medicine during the previous ages, and that comparisons of the headway made during the past few decades can be made only with that of the past two centuries rather than with that of earlier times

Editorial Comments

THE STERILIZATION OF MENTAL DEFECTIVES

At the last annual meeting of the American Medical Association an interesting commentary on the present position of sterilization in the United States was given by means of a special exhibit consisting largely of a series of maps and graphs. One of these was a map of the United States showing what legislation existed in each state. Considerable variation was evident. In some states there had been no legislative action, in others action had been taken and had then been found to be unconstitutional, while others still awaited the results of legal tests, in some the law seemed to be functioning satisfactorily, in some operative sterilization was made compulsory, in others it was voluntary. Two charts tabulated the states, showing the order in which the first sterilization statute was passed, what classes of individuals were subject to sterilization, and the agencies which had the authority to make the decision to sterilize.

One graph was devoted to the increase in population of institutions for mentally diseased since 1850, and of the mentally defective since 1904. An attempt was made in another chart to summarize the effect of sterilization of the insane and feeble-minded on race betterment, on the morality of the neighbourhood, and on the individual himself. Other maps showed the number and cost per capita of patients in hospitals for mental disease and mental defectives, and the institutions in California in which the insane or feeble-minded were sterilized. Finally, there was a list of the operations which induce sterilization, with or without unsexing.

The data for this exhibit were taken chiefly from a book entitled "Eugeneal Sterilization, 1926," by Dr H H Laughlin, but also included information gathered from reports of the United States Census.

The surgical aspect of the subject has been dealt with by Dr Dickinson in a paper entitled "The surgery of the insane and feeble-minded in California." In this he commented on the necessity of emphasizing the fact that steriliza-

tion did not involve the removal of any organ or the lessening of sex feeling, and referred to the amount of theorizing on the subject which had appeared in the press, in comparison with the collection of facts on the subject. He closed his paper with proposing a resolution that the Section of Obstetrics, Gynecology and Abdominal Surgery recommend to the American Medical Association that it organize or take part in an impartial and thorough investigation of sterilization from the point of view of medicine, surgery and preventive medicine.

The comment made on the subject by the Board of Trustees of the American Medical Association is worthy of note*. They recognize that the interest in legislation for sterilization is widespread, but the medical profession has not given the subject the study it deserves. "If legislation authorizing the asexualization of certain classes in the community does not accomplish the results that its proponents promise, the medical profession may have to assume its share of the responsibility, even though it has done nothing but stand idly by while the legislatures have acted. It seems timely to undertake a study of the field of eugenic sterilization asexualization now, so that the policy of the Association may be wisely determined."

H.E.M.

THE USE OF EPHEDRINE

Ephedrine is an alkaloid whose value in controlling attacks of hay fever or asthma is now fairly well established. It is not a specific remedy for these conditions any more than the very numerous therapeutic measures which in their turn have given relief. It does however most nearly approach that remedy which of all others generally used has the most rapid and beneficial effect, although short in duration, that is, epinephrin hydrochloride given hypodermically. But ephedrine possesses the not inconsiderable advantage of being effective when given by mouth, and when it does give

* *J Am M Ass*, 1928, xc, 1462

relief it does so for a longer period of time Ephedrine therefore commends itself rather highly in the relief of asthma

There are contra-indications to its use, however, which should be carefully pointed out These depend on the fact that its action is chiefly that of stimulating the sympathetic nervous system, thus causing acceleration of the heart action, along with which there is a temporary rise of the blood pressure Toxic doses will cause a fall in blood pressure and a depressor effect on heart muscle

The contra-indications to the use of ephedrine will therefore be mainly the presence of cardiac disease or of a high blood pressure, and it is important to insist upon this A case has been recently reported* of a patient with a history of hay fever who suddenly developed an acute attack of what was diagnosed as asthma He was given a prescription for ephedrine and within a space of 20 days took a total of 15 grams He then came under the observation of Drs Bloedon and Dickens who found him in a condition of cardiac decompensation with a dilated heart, and a right-sided effusion. They attributed this condition to the effects of the ephedrine, and the large quantity taken was probably enough to give rise to serious results There appear, however, to have been symptoms of cardiac disease beforehand

The case is instructive in emphasizing the dangers of an indiscriminating use of ephedrine Asthma is such a common disorder that no care is too great in enforcing caution in the prescribing of drugs which the patients can obtain for themselves Incidentally it may be remarked that ephedrine is now recognized to have very little value in asthma due to infective processes and in so-called "cardiac asthma" H.E.M.

THE RABIES SITUATION

A short account of the situation regarding rabies in Ontario was given in our July number (p 78) by Dr W D Hay, and reference was also made in the same issue to the review by Drs Rice and Beatty† of the prevalence of rabies in the United States

At that time no case of fatal human rabies in the present epidemic had been reported in Ontario, but we have now received details of one such case in the *Public Health Journal* (September, 1928, vol. 421), reported by Dr F Adams This was a little girl, aged four, who on or about the first of June of this year while playing with a cat was scratched and bitten on the left temple The wound was treated with iodine and no special attention was given to

the incident About two months later the child developed signs of involvement of the central nervous system and died five days later with well marked symptoms of rabies The post-mortem examination fully confirmed the diagnosis, the brain showed the microscopic changes typical of rabies and rabbits inoculated with the brain tissue developed the disease

Dr Adams points out that the local press had given much publicity to the subject of rabies and had described the transmission of the disease and the precautions it called for Attention, however, had been focussed largely on the transmission of rabies by dog bites, although a case of a rabid cat had occurred in June in Ontario, and three in Detroit

The case is worthy of note as emphasizing the difficulty in controlling the spread of rabies, a difficulty which is unusually great in the neighbourhood of the border cities in Ontario Detroit in particular labours under the disadvantage of exceedingly rapid growth, and its population is of many racial origins, more than fifty per cent have a mother tongue other than English The incidence of rabies in Detroit, is rapidly increasing in 1921 there were 30 cases amongst dogs, in 1927 there were 265, and in the first five months of 1928 there were 302 H.E.M.

THE MONTREAL HEALTH SURVEY

A special article summarizing the Report of the Montreal Health Survey appears in this issue It is noteworthy that all the newspapers of Montreal (French and English) carried the summary prepared for press release the last Saturday in September As long as prominent laymen, who accept professional guidance, continue to take interest in health work, we may rest assured that progress in this field is certain

This survey presents to Montreal a three-year program for health services, which is based upon accepted standards of health work as adapted to local needs The survey, which covers the country's largest metropolitan centre, will be of interest to all Canada It will also interest all communities, and may prompt them to enquire if such a survey might not be helpful in their own group One might ask whether or not it would be advisable for the Canadian Medical Association to consider the provision of a technical field health survey staff which would be capable of making such surveys or of acting as consultants in that capacity The medical profession is vitally interested in any program of health services presented to a community, and it may be that there is opening a field of national service which the organized profession should enter

† *Am J Pub Health*, 1928, vol. 421

THE OSLER LIBRARY

In a letter received lately from Dr W W Francis, who has charge of the cataloguing of the Osler Library, we are informed that every effort is being made to have the library packed and sent to Montreal before navigation closes. It is doubtful however, whether the catalogue which has already reached a volume of large dimensions will be through the press and ready for issue much before the end of the year. The annotations number nearly 8,000, and many of them have been written by Sir William Osler himself, and are his own comment on the book or on the writer.

In this catalogue we are informed the following groupings have been made. The FIRST SECTION includes all volumes either by or about the great innovators in science, including medicine in that term. The names in this group were decided upon by Sir William himself, but at the time of his death he was far from having obtained all the books in this section which he was anxious to have. Some sections are almost complete, such as the works of Vesalius, and of Harvey, and works on the introduction of anaesthesia. In other sections he failed, chiefly through his desire to obtain first editions. The SECOND SECTION is an alphabetical catalogue of the scientific works, for the most part medical, of writers who can hardly be regarded as holding the first rank. The THIRD SECTION contains the literary works of physicians and the quasi-medical writings of laymen, such as Burton's *Anatomy of Melancholy*. This section includes a very complete collection of the works of Sir Thomas Browne and the more important writings of Rabelais and of writers of his school of thought. The FOURTH SECTION is of an historical character and comprises works on the history of medical science and brief modern essays in special subjects with an historical character. The FIFTH SECTION contains biographies, many of which were given by Dr Adam from his collection. The SIXTH SECTION contains works on the bibliography of medicine and science generally.

The SEVENTH deals with menabula, and contains about one hundred and thirty-five fifteenth century works, not all medical. Many of these are very rare, and every year they are becoming more and more difficult to secure.

The EIGHTH SECTION is a collection of manuscripts, one of them is a Babylonian tablet on medicine dated about 500 B C. There are also a few mediæval manuscripts, but most of them are of more recent date.

The library contains about 7500 volumes, and the selection of its books was made by Sir William with an eye to their educational value.

The first section especially was brought together with the view of giving to the student a clear idea of the successive steps by which advancement was made in our knowledge.

A NINTH SECTION has been added containing many donations since Sir William Osler's death and includes a list of about 150 Oriental books and manuscripts presented to the library by Dr Casey Wood. A D B

NO 3 CANADIAN GENERAL HOSPITAL

The announcement is made that about the third week of November there will be published the official history of No 3 Canadian General Hospital (McGill), covering the work of the unit from the time of its inception under Col H S Birkett in the autumn of 1914 until its return to Canada in July, 1919.

The book which has been edited and compiled by Mr R C Fetherstonhaugh, historian of the 13th Battalion, Royal Highlanders of Canada and of the Royal Montreal Regiment, 14th Battalion, CEF, and has been checked by the Historical Section of the General Staff, Ottawa, will contain a foreword from His Royal Highness the Duke of Connaught, and will include twenty-one chapters of text, thirty-five full-page illustrations, and appendices giving the roll of honour, the nominal roll of the original unit, and the nominal roll of the reinforcements.

The story is written so as to include both the military and medical aspects of the Hospital and recounts many details of the work accomplished by the physicians and surgeons under Col Birkett, the late Col J M Elder, the late Col John McRae and those who succeeded them. The book will be printed on laid paper in large clear type and will be issued in cloth-bound and de luxe editions selling at \$5.00 and \$10.00 respectively. The editions which are limited in number may be obtained through the distributors—Burtons Limited, 597 St Catherine St W, Montreal.

R C FETHERSTONHAUGH

THE EDITOR

The friends of Dr A D Blackader, the senior editor of the *Journal*, and they are many throughout the length and breadth of Canada, will regret to hear of his recent serious illness. At the time of writing he was still confined to the house but we are pleased to be able to announce that he is well on the way to convalescence. All who know him, including his colleagues on the editorial staff, will join in the hope that he will soon be restored to his accustomed health and vigour. A G N

THE EVOLUTION OF CLINICAL MEDICINE AND SURGERY IN RELATION TO THE PRESERVATION OF HEALTH AND LIFE*

BY FRANKLIN H. MARTIN, M.D.

Chicago

After thanking the American College of Surgeons for the honour done him in electing him President, Dr. Martin said that in his address he would attempt to portray the present evolution of the art and science of medicine, and the part that our profession and the public should have in guiding its successful progress.

Those who visualized the American College of Surgeons, organized it, and have been responsible for its administration, realized from its inception that just to organize another surgical association, just one more academic society, was not a reason to warrant its creation. The College, to justify its existence, would have to assume the responsibility of building for broader science, for more worthy practice, for interest in sustaining the traditions of the greatest profession, and by the example of its Fellows and through open discussion, impress upon the public the significance of scientific medicine as the one authority qualified to maintain the health, and insure the wholesome living of all people.

It was a bold announcement—the declaration by the Founders of the College at its inception.

Among the learned professions, medicine has no equal in longevity, in continuity, in ideality, in disinterested service, and in accomplishments. For twenty-five centuries, medicine exhibits a clear history. Its spiritual and moral creed—the Hippocratic Oath—announced at that early beginning, has been and is as fundamental in the guidance of the true physician as the Sermon on the Mount (first uttered five hundred years later) in the guidance of the true Christian. Spiritually, morally, and scientifically, in all civilized countries scientific medicine is outstandingly the recognized authority in the prevention and cure of disease. Like the great religions of the world, it recognizes no geographical bounds, but, unlike the great religions, it has no division of authority.

A recital of the long chain of distinguished men of medicine, with many links centuries long, reveals an unmistakable continuity. To mention them individually, is to count the beads of a great rosary, one by one, each bead a jewel of rare worth and beauty. It is a record of singular interest. Every physician is assumed to have a knowledge of this history, but he should know it accurately, and for protective information the

cultural education of each person—man, woman, and child—should include facts of medical history.

For centuries the art of medicine was paramount. This art was based on records which represented careful study of diseases, the effect of drugs, and the performance of operations in dire emergencies only. Familiarity with the action of drugs was discovered and developed to an astonishing degree of exactness, and the proficiency with which the experienced practitioner influenced the different shades of diseases would excite the admiration of the skilled practitioner of our present ultra-scientific age. Like a master musician, the physician of yesterday studied and knew his organ, and no note was too subtle for him to reproduce.

The nineteenth century saw the development of the pure sciences. Rapidly these were absorbed by the medical profession, and now more than ever we may say that we practice the science as well as the art of medicine. Long experience in recorded observation is not the only basis of our accomplishments, but as well the mathematical certainties of pure science and its instruments of precision.

First and foremost are the scientific accomplishments that have definitely modified and controlled specific diseases, and incontrovertibly conserved life and health in a revolutionary manner: the work of Pasteur, and its adoption by Lister in the development of antiseptic surgery, the outstanding pursuits of Koch in modifying tuberculosis, the epoch-making researches by Behring, Roux, and Klebs in controlling diphtheria, the indefatigable labours of Ehrlich in furnishing a remedy for the spirochætal diseases, the achievements of Roentgen, of Eberth in well-nigh exterminating typhoid fever, the painstaking accomplishments of Bruce in sleeping sickness, Ross and Laveran in malaria, our own Reed, Finlay, and Gorgas in yellow fever, Banting in diabetes, and the Dicks in scarlet fever. These specific accomplishments have resulted in saving more lives each year than were lost in the Great War.

There are certain other diseases that reap a large death harvest and a much greater disability. Though we have not a specific for each, we have definite proof that they may be modified or cured if discovered early. These include the degenerative diseases, insidiously begun in middle life and exaggerated in old age, notable among them, cancer, with a mortality of 115 in every 1,000 deaths, though if recognized early it may be cured, heart disease, that makes its deadly swath in individuals in the most productive period of life, 185 to every 1,000 deaths, may be modified if early recognized and appropriately treated, diseases of the kidneys and blood vessels, with their harvest in middle life of 110 in 1,000 deaths.

* Presidential Address (abridged) delivered before the American College of Surgeons, Boston, October 8, 1928.

Preventive medicine, or the early application of curative measures in these diseases, would save thousands of lives each year

So to extend longevity to any material degree, we must first discover the cause of, and secure a remedy for, degenerative diseases

The degenerative diseases cause one-third of our deaths. They are definitely influenced by concurrent incidents, as habits of living, strenuous mental activities, improper diet, excessive use of stimulants, particularly alcohol, lack of proper exercise and recreation, and infectious diseases that thrive on a weakened resistance. They are the result of age or its equivalent—excessive work

The science of chemistry, endocrinology, biology, physiology, clinical pathology, and basic metabolism, is tackling and solving new problems every day. Adrenalin, thyroxin, insulin, and pituitrin are examples of exact and progressive accomplishments. Undoubtedly the substances that will control the degenerative diseases are now in the making

Scientists today are mining the materials, men of vision are fitting these materials into practicable theories, and practical men are straining at their leashes ready to utilize these materials and make great visions come true

PUBLIC HEALTH

We know to a mathematical certainty the contributions of scientific medicine toward public health in comprehensive hygienic regulations and general sanitation. The findings of scientific medicine, through civic and other governmental authority, are applied to purify the water supply, to dispose of sewage, to protect and conserve the purity of food, to ventilate public buildings and places of amusement—gifts which the lay public has accepted almost unanimously, and all civilized countries realize the extent to which life is protected and wholesome living insured through the provisions of scientific medicine

Ours is an unique heritage from a most ancient and accomplished profession. Are we, as trustees, doing our utmost to perpetuate and extend these doctrines? Is the public unmindful of its legacy through ignorance, indifference, or false teaching? Whose is the paramount responsibility to supplant ignorance with knowledge, indifference with interest, and false teaching with truth? The practitioners of medicine themselves!!!

In this review I have endeavoured to ascertain what would be the result if the doctrines of scientific medicine were applied in a maximum degree toward the conservation and preservation of personal health, and toward the alleviation and cure of existing disease. It must be obvious that the effect in prolonging life would be phenomenal, and in extending wholesomeness of living, and happiness in pursuit of life, inestimable. Our past and present methods have confined our activities to curative medicine, almost to the exclusion of preventive medicine

Though it be impossible to speak with exact-

ness, it is a safe assumption that of the 130,000,000 people in the United States and Canada, one-half of those of reasoning age have no familiarity with the simplest fundamentals of the laws of health. While this proportion of our population is ignorant of the importance of health laws, it is again a safe assumption that false teachings by propagandists, and one or another reasons have led at least another one-fourth of our reasoning population to develop a positive antagonism to scientific medicine, and definite resistance to its services. Those who oppose scientific medicine thrive more or less successfully according to the advertising zeal of their leaders, they represent the various sects, cults, and organizations of proprietary and patent medicines

If it is true that one-fourth of our population of reasoning age represents active opposition to curative medicine, and succeeds in avoiding its ministrations, here is a sound basis on which to estimate the effect of this on the health and mortality of the whole population

Thus our favourable showing is possible with non-resistance or indifference of one-half of the population of thinking age. Estimating that one of every four resisted the services of scientific medicine—refused vaccination for smallpox, antitoxin for diphtheria, and appropriate prophylaxis in the other preventable diseases—a large proportion of the present death rate in these diseases is avoidable and may be attributed to this resistance. An ultra-conservative estimate (under accepted methods of statistical study and mathematical calculations) will attribute to this one sin of omission 8,790 6 avoidable deaths in 1925, and 87,906 avoidable deaths in the ten years, 1915 to 1925

The remedy is obvious. There must be continuous education. The fundamentals of scientific medicine, its practicability and acceptability, should be taught in the primary classes of our public and private schools, as early as the seventh or eighth grades. The fundamental principles of scientific medicine should occupy the same relative position of importance in the grade schools as grammar, general and physical geography, lower mathematics and English literature. The influence of these principles on personal and public health should be emphasized and reiterated, and knowledge imparted of the laws of general hygiene and sanitation

A number of experiences in addressing school children convince me that education in the basic principles of scientific medicine would be accepted by them with great enthusiasm, and the heaven there sown would be of incalculable aid in lessening the existing ignorance and indifference toward the maintenance and promotion of better health. Moreover, in a dignified and proper manner it would be a potent factor in combating misinformation, which, uncurbed, develops into opposition to the truths of scientific medicine

Preventive medicine and its counterpart, periodic health examinations, have been discussed since the earliest days of medical science. If

scientific medicine has established its right to assume the responsibility of supervising and maintaining the health of the people, it is a foregone conclusion that it should examine each and every individual at definite intervals, and give advice based on the findings

Practical work along this line has been enthusiastically developed by the Metropolitan Life Insurance Company. Special semi-public organizations, conspicuously the National Tuberculosis Association and the American Society for the Control of Cancer, the former twenty-four years ago, the latter sixteen years ago, began to urge periodic health examinations so that the signs of the respective disease in which they were interested might be discovered early, and later their example was followed by the American Child Health Association, the American Social Hygiene Association, the American Heart Association, *et cetera*. Naturally it soon became obvious that preventive medicine could be more systematically advanced if the public were educated to accept a comprehensive periodic examination that would reveal the early sign of any disease instead of some particular disease.

The Great War emphasized the wisdom of thorough physical examinations, as every country which entered the conflict arbitrarily exacted a medical examination of its soldiers.

The medical corps of the Army, under General Gorgas, alone accepted for service, medically, 4,500,000 of fit men, and to secure this number it was necessary to examine approximately 7,000,000 young men. The difference in these figures represents those who were unfit.

These demonstrations with examinations for special diseases, gave great impetus to the propaganda in favour of all-round periodic examinations. In 1919 and 1920 this organization, the American College of Surgeons, organized its sectional meetings, since which time we have held sessions in practically every state of the United States, and every province of Canada. The principal innovation is the carefully planned meeting for the laity at which, in simple language, the layman and woman are given information on the fundamentals of scientific medicine, and especially the advantage of periodic health examinations. The Gorgas Memorial Institute of Tropical and Preventive Medicine was organized in 1921. As the activities of the Memorial have developed, it has more and more urged upon the public the importance of seeking an annual health audit by the family physician.

EDUCATED PILOTS

The public should know what we know—that in a large number of our states, individuals are licensed to practice the healing art who are utterly ignorant even of the barest fundamentals of scientific medicine, cultists, some of whom have not even a rudimentary knowledge of the basic sciences, of anatomy, physiology, chemistry, bacteriology, pathology, diagnosis, or the other primary essentials of a medical education,

cultists, some of whom utterly ignore or denounce the necessity of possessing any knowledge whatsoever of these indispensable requirements. The various cults, under sundry names, have gained the sympathy of legislatures. By subtle sophistry, they have passed laws which require farcical examinations in one or another pathy or cult, authorized license to practice medicine or even surgery, and have caused them to be recognized as legal practitioners of the healing art, with all of the rights and privileges of the scientifically educated physician.

Of the forty-eight medical practice acts authorized by the individual states of the United States, only four require that an individual, to be licensed to practice the healing art, shall show by examination that he has a knowledge of the basic sciences upon which, obviously, the practice of the healing art should be grounded. This means that in the other forty-four states of the United States not requiring the basic science examination, only the graduates in scientific medicine meet these qualifications.

The basic science law requires that every practitioner of the healing art shall pass successfully an examination in the basic sciences before he is eligible to present himself as a candidate to the state board of examiners for a license to practice medicine or the healing art in any form recognized in the medical practice act of the respective state. The first section of the "Enacting Clause" reads

BASIC SCIENCE CERTIFICATE REQUIRED No person shall be eligible for examination or permitted to take an examination for a license to practice the healing art or any branch thereof, or granted any such license, unless he has presented to the licensing board or officer empowered to issue such a license, a certificate of ability in anatomy, physiology, chemistry, bacteriology, pathology, diagnosis and hygiene (hereinafter referred to as the basic sciences), issued by the state board of examiners in the basic sciences.

In obtaining thorough health examinations, how can we insure the independence of the family doctor, the personal internist, and the favourite surgeon? How insist upon a thorough and complete health audit, save the public from the exploitation of unworthy groups, stock companies, or even the well organized clinics or well equipped dispensaries or hospitals, and yet not lose to the personal physician his control of his own legitimate clientele? On this point even the exponents of the health audit have been most apprehensive, and their consternation has led them almost to the point of abandoning the program, lest in spite of its advantages the independent practitioner be put out of business.

The American College of Surgeons is successfully working out a remedy, a supremely practical solution of the problem, that will be satisfactory equally to the laity, the independent practitioner, public health officials, and the hospitals. Obviously, the difficulty lies in the fact that no one practitioner, regardless of ability and eminence, can individually overcome the prohibitive diffi-

culties and make a complete health audit, unless he has at his command competent aids, and intricate scientific apparatus and laboratories

Where is the environment that will remedy this difficulty? Well organized groups, organized clinics, *the standardized hospitals*

THE HEALTH INVENTORIUM

The "Health Inventorium" is planned by the College to meet this exigency. The suggested plan was submitted to one-tenth of the 1,805 hospitals in the United States and Canada on the approved list of the College in 1927. Almost without exception the plan was accepted. Thereupon, the plan was submitted to all hospitals on our approved list in 1927, and finally there is a thorough discussion of the subject at our hospital conference during this session of the Clinical Congress. The fundamentals of the plan have met with almost unanimous approval.

The detailed plan can be summarized but briefly here. It is as follows:

- 1 Every standardized hospital shall furnish an examining room or rooms, to which any legalized practitioner, who is a member in good standing of his respective county medical society and the American Medical Association, may bring a patient for examination. There shall be no charge for the examining room.

- 2 The hospital shall furnish to the practitioner every facility in the way of aids, consultants when necessary, laboratory tests, etc., as will insure a comprehensive audit of his patient's condition.

- 3 The charge for the required laboratory tests shall be nominal, and a maximum of actual cost.

- 4 The physician shall render to the patient a bill covering his fee for the examination, and where there is a charge for laboratory services, he shall be responsible to the hospital for its payment.

- 5 No hospital shall accord these facilities to any individual who is not accompanied by his or her doctor, or who does not carry a letter from his or her doctor in which certain services are requested.

- 6 An individual who applies for an examination and who has no physician should be referred to a duly appointed, disinterested committee consisting of a representative or representatives of the county medical society and the standardized hospitals of the community, and this committee shall advise the patient in the selection of a physician.

- 7 Except in dire emergency, no hospital shall treat a patient who was examined in the Health Inventorium, except by request or consultation with the referring physician.

THE DEMAND FOR HEALTH EXAMINATION AND ITS ACCEPTANCE

It is not surprising that life insurance companies should advocate and be ready to lend financial support toward popularizing periodic

health examinations. This commendation only emphasizes their importance. They recognize the movement as a substantial business asset, as it will extend the life of their policy holders, reduce the cost of insurance, and incidentally substantially increase profits. Are not these facts, substantiated by business sagacity, evidence that you and I, as policy holders, too, will profit in longer life and better health?

The approximate increase in demand for periodic health examinations with companies which give figures for 1920 and 1927, ranges from the encouraging figures of 549.5 per cent to 3,867 per cent.

Considering the short time occupied in the experiment, this is a showing that demonstrates a substantial interest by the people. Notwithstanding a reluctance on the part of not a few policy holders to accept the service on the ground that it is not an entirely disinterested activity, it is a movement that will develop incalculable health conservation.

Our College has been asked by a number of the important indemnity companies and industries who must provide protection to their employes to make a survey that will assist them to give the highest degree of protection to the employed in industry. As a result, through our Board on Traumatic Surgery, we made careful inquiry into the protective measures and health care that are provided to the great number of employes in large corporations.

While indemnity companies and state laws furnish protection to men who labour in the industries, in the last analysis, such indemnity protection is financed by the industries themselves. Wisdom and efficiency have led a considerable number of the larger corporations who employ labour to adopt methods of self-protection by furnishing to their men every facility that scientific medicine offers in the way of preventive and curative health measures, and similar facilities are provided also to their entire administrative force. The beneficent effect of this system in preserving health and furnishing the best surgical and medical aid in case of injury or illness is not of less importance because it results in a financial saving to the industries which furnish the aid, but it is the most substantial and effective commendation of scientific medicine and its relation to personal health.

Our survey indicates that this form of humanitarian service has increased enormously since 1920.

Labour has not been slow to recognize the importance of this movement. Samuel Gompers, outstanding statesman of labour, during his lifetime earnestly and continuously urged his great army of followers to ally themselves with scientific medicine. His worthy successor, William Green, the present President of the American Federation of Labour, is backing the program of our College to improve the status of industrial surgery and medicine. There is no power greater than organized labour to influence the advance-

ment and extension of scientific medicine. Following the demonstration of the care of men in industry, especially in the production of munitions and other materials for warfare, the average increase in yearly health audits among labour men, based on our survey, is approximately 95 per cent since 1920. This favourable showing is possible because most of the industries surveyed had similar service in 1920.

As early as 1905, Theodore Roosevelt, with his alert mind, looked with appreciative vision upon this problem of keeping physically fit, and, characteristically, he acted. Why have weak links in the United States Army, Navy, Marine Corps, and Public Health Service when by proper medical supervision the unfit units could be weeded out? From that time to the present the United States soldiers, sailors and marines have been submitted to regular physical examinations. The benefits of that program are now extended to the members of their families. By this regulation alone, over one million citizens are examined yearly and receive the benefits of preventive medicine.

In the last ten years, in my travels and talks at sectional meetings of the American College of Surgeons, I have found well organized educational departments in practically every state of the United States and every Province of Canada. With few exceptions primary schools, and authorities in higher education, are careful to note the physical well-being of pupils. It is an exception if the authorities do not insist upon vaccination against smallpox, examination of the throat, tonsils, hearing, and eyesight.

Our survey, done by questionnaire, which covers the health activities of the health authorities of eight cities of the United States having a population of not less than 250,000 each, may be summarized thus:

We have discovered that there is a growing interest in periodic health audits on the part of apparently healthy laymen, women, and children. We have learned our profession's wholesome interest in this subject.

With better facilities furnished to the general practitioner, through our Health Inventorium, and the increased demand for periodic health examinations on the part of the public, this preventive measure for conserving health and life will make notable progress in the next few years. Briefly, we note that there has been an increase, between the years 1920 to 1928, on a conservative estimate of reports, of approximately 1 to 1,000 per cent in examinations of apparently healthy individuals, that of the individuals examined, who were apparently well, from 1 to 100 per cent were harbouring unsuspected disease.

CURABILITY OF THE DEGENERATIVE DISEASES

The diseases of middle life and advancing age, already referred to, are now attracting the attention of scientific medicine. What are they? At what age do they manifest themselves? Can

they be postponed by thorough periodic audits? If they exist, can they be influenced by curative measures? And can the average limit of old age be advanced by careful surveillance, and scientific management?

These questions are important, not only to the scientific practitioner of preventive and curative medicine, but to every person, whether of early, middle, or advancing life, 33 per cent of whom, at the present time, succumb unnecessarily early, and in the interval between birth and death suffer needless ills that destroy the pleasure of wholesome and healthful existence. In the second part of our questionnaire this subject was dealt with most interestingly by 228 practitioners who honoured us with replies.

The range of years for the development of degenerative diseases appears to be from 15 to 75, with a large preponderance from 35 to 50 years.

216 replies were recorded, 73 report much good accomplished, 66 report modify and postpone (of these 30 included "cure" and 40 "prevent"), 35 report prolong life, increase efficiency, 6 report no benefit, 15 report fair, 13 report very little good, 8 report questionable.

The replies also, most of them from the leading, picked physicians of the United States, indicate a very great interest in degenerative diseases, and a belief that their course could be modified and postponed through these examinations.

FINAL SUMMARY

(a) Estimated number of periodic health examinations of apparently healthy individuals—in 1920, 5,000,000, in 1927, 20,000,000, (b) One-third of the deaths in 1925 (or 502,083 deaths) are attributable to degenerative diseases of middle life and old age, (c) Degenerative diseases manifest themselves at average age of 45 years, (d) 236 replies from eminent internists, and 18 replies from general practitioners, indicate yearly examinations would modify and postpone the degenerative diseases, and increase longevity and the maximum old age limit, (e) 35 per cent of apparently well individuals receiving periodic health examinations are found to harbour some form of unsuspected disease or physical defect, (f) 90 per cent of our replies from internists and outstanding clinics reveal that patients are advised to submit to periodic health examinations, (g) Labour in industry, employees in governmental and civic organizations, pupils in elementary and secondary schools, colleges and universities, practically all receive and welcome some form of periodic supervision, advice and service, and at least an additional 17,500,000 receive complete periodic examination service, and an estimated additional 3,000,000 men and women, not included in the above, brings the grand total to 20,500,000.

The above figures, while not conclusive, indicate the enormous interest that is developing in the subject of periodic health examinations. However, this is not a guarantee that all of these examinations now are to the highest degree com-

prehensive and efficient. The figures do indicate the lay public's receptivity to this important innovation. And their acceptance of the ministrations of scientific medicine places upon the profession a responsibility that should induce us to give a one hundred per cent service.

THE INFLUENCE OF THE PHYSICIAN WITH THE PUBLIC

A mistaken policy of silence, and a tradition of non-communicability in discussing the health problems of our patients, has militated against our full influence with the public. No profession, not even the ministry, can more effectually guide a large proportion of the community on a private or public policy. When we fail to exert this prestige, it is the fault of our profession and not of the public.

We have had three outstanding illustrations of this statement:

1 In 1920 the irregular practitioners of the healing art, the patent medicine venders in California, backed by subsidized newspapers, attempted to prevent animal experimentation in the teaching of medicine within the state. The scientific medical profession was aroused, the educated and sane people of that great state rallied to their support, and the antagonists of scientific progress were completely routed.

2 In 1922, a similar belligerent campaign against scientific medicine occurred in Colorado. For a time it appeared that the qualified doctors would have to forfeit those requisites which are indispensable to the teaching of their profession, and that the legislators of an important state were to turn thumbs down on the progress of civilization. Again, the scientific medical profession was aroused, exerted its influence, took the public into its co-operation, changed the tide toward sanity and common sense, and completely routed the opposition.

3 In 1921, Massachusetts, indifferent to the growth in its midst of the most subtle forms of irregular practices, found these same cults, who repudiated the conventions of civilization and considered themselves strong enough to terminate the teaching of scientific medicine, were organized to stop animal experimentation in the teaching of medicine. Slowly, but eventually, the profession of scientific medicine was aroused—they gained the co-operation of their patients, and together they routed the knights of unrighteousness beyond redemption.

The profession of medicine exerts a powerful influence, and can, if it will, convince at least 75 per cent of our people that it is their inalienable right to be kept well, and that the scientific medical profession is the one authentic, accredited, and competent agency equipped to keep them well so far as is humanly possible.

Lay people, in the majority, are waiting for us to take the lead in the practice of the healing art, to halt our mysterious methods, and give them face to face facts and guidance so that they may be maintained in good health.

GENERAL SUMMARY

1 The profession of scientific medicine, organized before the advent of Christianity, is the oldest of learned professions. Spiritually, morally, and scientifically, in all civilized countries, it is outstandingly the recognized authority in the prevention and cure of disease. Like the great religions of the world, it recognizes no geographical or political bounds, but unlike the great religions, it has no competitors. It is the one authority in scientific medicine recognized by all civilizations.

2 For centuries scientific medicine was practiced as an art and every scientific truth employed to make its authority more worthy and reliable. With the development of the exact sciences, it has strengthened its art and made more definite its authority and accomplishment by appropriating the proved truths of modern science, until it is now known, and properly so, as the science of medicine.

3 As we have shown, problems of disease, one after another, have been and are being conquered, and not only the trained physician has this knowledge, but the educated layman, too, is prepared to accept preventive and curative scientific medicine as the recognized authority, and rapidly the public is improving the opportunity to keep fit and submit to periodic surveillance by the practitioner of scientific medicine.

4 The thorough physical examination of millions of soldiers in the Great War, proved the value of scientific medicine, and convinced millions of men of the wisdom of a periodic physical audit, under the supervision of scientific medicine, to keep themselves well. Through systematic propaganda advocating preventive medicine to conserve personal health, the general public has become aware of the value of periodic health examinations, labour has been convinced of the value of keeping well, and the industries, as an economic asset, have been induced to establish scientific facilities to keep their employees to the highest degree in good health.

5 Change of opinion has been wrought in the minds of the laity, in their attitude toward the relative wisdom of periodic audits to preserve health, rather than to wait for illness to make evident a possible incurable condition. A wholesome evolution in the practice of medicine is resulting, and it promises to become a boon that will preserve personal health to the maximum degree, and afford satisfaction to the scientific practitioner of medicine because of ability to practice his profession with greater precision and success.

6 The American College of Surgeons has occupied an important position in this movement, which must command the support of the teachers of medicine, the practitioners of medicine, the authoritative societies of medicine, the journals of medicine, and through all dignified means of publicity, it must educate the public to the necessity of co-operation with scientific medicine.

if they are to be protected from illness, and if the happiness of their lives is to be enhanced

7 Statistics show that 25,112,309 individuals in the United States are employed in the industrial occupations. According to our limited survey, one-half of these individuals receive medical service and periodic supervision, conservatively we estimate that of the total employed only one-fourth receive this service, or 6,278,077

In the U S Army, Navy, and Marine Corps 250,188 of their personnel receive this thorough service, which is extended also to the members of their families. On the basis of four members in each family, this brings the estimate to 1,000,752

There are in the elementary and secondary schools, universities, colleges and professional schools, (continental United States) 27,381,816 pupils and instructors. Our survey shows that three-fourths of these receive medical service and periodic supervision, but conservatively we estimate only three-eighths, or 10,268,181

SUMMARY

Individuals in industrial occupations who receive complete medical service and periodic supervision (estimated)	6,278,077
U S Army, Navy, and Marine Corps, and members of their families (estimated)	1,000,752
Pupils and instructors in elementary and secondary schools, universities, colleges, and professional schools of continental United States (estimated)	10,268,181
Further, it is estimated that an additional 3,000,000 men and women, not included in the above, receive complete and thorough periodic health examinations	3,000,000
Total in these four classifications who receive medical service and periodic supervision (estimated)	20,547,010

8 Through our recent research and study with the industries, labour, insurance, indemnity companies, governmental, state, county, and civic authorities, our universities, colleges, high schools, and primary schools, and others in their preventive health activities, from our direct questionnaire to our most influential practitioners of medicine, there is convincing evidence that the public is rapidly accepting the policy of co-operation with scientific medicine, and the practitioner of medicine is more and more willing to do his part, all of which offers conclusive proof that within the next ten years, the momentum of this evolution will find 30,000,000 of our people accepting the program of early health audits to conserve personal health, as readily as they now accept the protection provided to the masses by public health activities

9 The health inventory—which brings into the strong trinity of co-operation the scientific medical practitioner, the standardized hospitals, and the laity—when thoroughly understood

and accepted, will insure to every practitioner adequate facilities to make thorough examinations and to the public a thoroughly reliable service

10 The questionnaire to internists and general practitioners reveals a keen interest in observation and study of the insidious diseases of middle and advancing age—the degenerative diseases, and most of them have expressed the definite opinion that yearly or semi-yearly health examinations will reveal these diseases in their incipency, afford opportunity to modify and postpone the progress of many of them, and definitely prevent the development of some of them. Inasmuch as one-half of our yearly deaths are attributable to diseases which reap their harvest in man's years of greatest usefulness, the significance of this authoritative information is apparent

11 This review of the evolution of the progress of clinical medicine and surgery emphasizes our responsibility as practitioners of medicine. We must give service to the utmost of our ability, and with the lay public must rest the responsibility of accepting it. Volunteer acceptance will

- (a) Preserve rather than restore the health of 100 per cent of the people, to the greatest degree possible through the sciences,
- (b) Require that practitioners of medicine be educated in the basic sciences before they may be licensed to practice the healing art,
- (c) Make readily available to medical schools all facilities necessary to teach scientific medicine, and to preserve modern research methods in the laboratories by animal experimentation,
- (d) Employ all dignified publicity methods, guided by scientific medicine, to enable the public to recognize the reliability of scientific medicine and to distinguish it from the subtleties of uneducated pretenders and imposters

12 This review estimates that approximately one-fourth of the laity are now indifferent to the benefits of scientific medicine, and that approximately another one-fourth are antagonistic to it, the victims of sophists, quacks, and other unscientific practitioners. While this affects detrimentally the individuals of adult life whose wisdom should guide them to choose judiciously, and with whom it is futile to protest, unfortunately it also affects their innocent children and dependents, and results in much unnecessary sickness and many premature deaths. The increased health rate, and the number of lives saved in 25 years of this century by the application of scientific medicine, proves that the refusal of this large proportion of our people to accept our aid without doubt accounts for much unnecessary illness and suffering, and at least 17,581 2 preventable deaths each year

13 More than two-thirds of our people morally and spiritually favour the 18th Amendment to the Constitution of the United States. In spite of the injudicious administration of this 18th Amendment, which has resulted in an orgy

of law-breaking, of self-indulgence, and ridicule on the part of the other one-third of our citizens, the foundation has been laid for a demonstration of race betterment and extension of life that will astonish the world

14 It is my wish that this review may aid to convince the people that one-half day each year should be set aside for a comprehensive health audit of each member of every family. As physicians we know the essentials, and the details of scientific medicine. We believe that the layman and woman from childhood should have a convincing knowledge of the essentials of preventive medicine. This knowledge must be imparted by dignified publicity methods, by teachers who are educated physicians. If this reasonable program is accepted and acted upon (and the present attitude of the people indicates that it is being accepted and adopted), I predict that our estimate of longevity will show an increase from 58 years in 1920, to 65 years in 1930, and what is of greatest importance, a decrease in preventable illness that will add immeasurably to the wholesomeness and happiness of more than 100 millions of people in the United States and Canada

THE MONTREAL HEALTH SURVEY

By A GRANT FLEMING, M B

Montreal

Montreal citizens in increasing numbers have, for some years, been dissatisfied with health conditions in their city. Voluntary health organizations and other groups have striven from time to time, by education and demonstration, to awaken the general public and the city administration to the situation. The result of their efforts has been an increasing interest in and understanding of health conditions and a desire to take some action to rectify the state of affairs. Added to this was the stimulus of the late typhoid fever epidemic.

The Montreal Anti-Tuberculosis and General Health League deemed that the opportune time had come for making a health survey of Montreal, and that it would be advisable to have such a survey sponsored by a group of representative business and professional men, who, as a group, were not associated with any particular health agency. An invitation to form such a committee was extended through Sir Arthur Currie, Chairman of the Health League. The Montreal Health Survey Committee is composed of the following: The Right Honourable Lord Atholstan, LL D, E W Beatty, KC, LL D, Lyon Cohen, Louis S Colwell, Sir Arthur W Currie, G C M G, K C B, LL D, Ernest R Décary, N P, Hon P R du Tremblay, M L C, J T Foster, J A Francoeur, Sir Charles Gordon, C B E, Louis de Lotbinière Harwood, M D, Sir Herbert S Holt, LL D, Beaudry Leman, C F Martin, B A, M D, LL D,

J W McConnell, Edouard Montpetit, LL D, Hon J L Perron, KC, M L C, Hon Donat Raymond. A technical committee of three Montreal health specialists, Doctors J A Baudouin, A Grant Fleming, and R St J Macdonald, was formed to collect the material to be studied to prepare a report based on this material and to make recommendations.

By consulting with individuals and groups working in the various agencies engaged in particular health functions, it was possible to gather practically complete information on the services being rendered, and so to verify the quality and extent of the services as indicated in the reported figures. The staff of the General Health League was placed at the disposal of the Committee for work in connection with the survey, the cost of the survey being met by the Health League.

The Field Staff of the Committee on Administrative Practice of the American Public Health Association was engaged in a consultant capacity, and the technical committee acted under their guidance and direction. The appraisal of City Health work was made by the consultants, using the Appraisal Form for City Health Work of the American Public Health Association. Doctor C E A Winslow is chairman of this Committee, Doctor W F Walker, Field Director, and Miss E L Smellic, Chief Superintendent of the Victorian Order of Nurses for Canada, was attached to the Field Staff for purposes of the Montreal Survey.

Assistance was received from many individuals and organizations. Special reference is made in the report to such assistance from Dr S Boucher, Director of the Department of Health, from Dr F G Pedley, in Industrial Hygiene, from Dr W T B Mitchell, in Mental Hygiene. The full report is being published through the courtesy of the Metropolitan Life Insurance Company, and will be distributed shortly.

From the Report, the following items have been selected as of special interest to the medical profession.

A comparison of expenditures of Municipal Health Departments for 1927 shows Montreal's expenditure as 39 cents per capita, and the average of twelve large cities of the United States as 78 cents per capita, ranging from 50 cents to \$1.18. The total health expenditures in Montreal by official and voluntary agencies are given in tables and show the total expenditure as \$1.81. This, however, includes the cost of bedside nursing services and of the hospitalization of communicable diseases and tuberculosis. If this be deducted, an expenditure is shown of 69 cents per capita, by voluntary and official agencies, on what are considered as health expenditures in most communities.

A study of mortality trends for Montreal shows an unmistakable saving in lives, particularly in the early age group. Judged with other cities of comparable size, the condition is not satisfactory. The tuberculosis death rate of 126.

the infant mortality rate of 113, the total diarrhoea and enteritis deaths (under two years) of 870, are high in comparison with other cities

The appraisal is based upon standards arrived at after careful and complete studies of many cities. The standard set is such that 25 per cent of the cities studied would attain a perfect rating. The goal is not, therefore, idealistic and unobtainable, but one which may be closely approached by any city with a well-planned and properly directed public health program

SCORE OF PUBLIC HEALTH ACTIVITIES

Activity	Montreal's Percentage
Vital Statistics	72
Communicable Disease Control	54
Venereal Disease Control	60
Tuberculosis Control	55
Maternity and Ante Natal Hygiene	38
Infant Hygiene	64
Pre School Hygiene	88
School Hygiene	49
Sanitation (Water and Sewerage)	94
Laboratory	34
Milk Control	57
Food Control	53
Popular Health Instruction	45
Average Total	62

This score means that the combined effort of Montreal's official and voluntary health services measures only about two-thirds of the best examples of such services in other cities of comparable size

Certain activities, such as mental hygiene, industrial hygiene, and cancer control, the public health practices concerning which have not been sufficiently standardized to permit of appraisal, are not scored, but are dealt with in the report

RECOMMENDATIONS

It is recommended that the island of Montreal be organized as a health unit, because of the advantages obtainable from a uniform control of this natural unit of administration. In the event of the adoption of a Borough System of government for the island, it is argued that Public Health should be one of the centralized services

It is recommended that where the public authority delegates to voluntary agencies its responsibility for the care of the public health, the city and the province each contribute one-third of the agencies' expenditures on health work of proved value, carried on according to a standard set by the public authority. In any case, the sums of money which are distributed should be allocated on a service basis

In a discussion of "Whom Should the Department of Health Serve?" it is stated that Community Health Service should be offered on a community basis without regard to the economic condition of the person served. Also, that in advising this, it is intended that physicians in health clinics be paid for their services

It is recommended that a Board of Health of

five members be instituted. That the University of Montreal and McGill University each nominate two members who, together with the Chairman of the Executive Committee of the City Council, shall be appointed as the Board of Health

The advisability of dividing the city into sanitary districts with a health centre in each district, and the advantages of a bi-annual census based on these districts are emphasized

To provide the Department of Health with prompt notification of births, provision for which is not made under the present system, it is advised that the reporting of births by physicians be enforced, and that a fee of 15 cents be paid for each report

The reporting of communicable diseases is much below the standard of other comparable cities

In regard to diphtheria immunization, it is recommended that, in addition to free distribution of the material for immunization, the sum of \$1.00 be paid to physicians for every pre-school child they report as having immunized. The cost to the city of hospitalization of diphtheria cases is more than \$100,000.00, which would pay for the cost of immunization of the present pre-school group at once, the cost thereafter would be \$20,000.00 per year

The establishment of culture stations throughout the city, a public health laboratory service for all citizens, and free biological products, are recommended

It is recommended that the use of silver nitrate, or some similar solution, in the eyes of the new-born be required, that diphtheria cases and contacts be released only upon negative cultures, instead of at the end of a fixed period as at present, the release from supervision of typhoid fever cases to be determined by negative cultures of stools and urine

Approximately one per cent of the population come as new cases each year to the Venereal Disease clinics. It is recommended that the reporting of cases by number be required by law, and also provision for compulsory treatment or isolation of those failing to take treatment in a satisfactory manner. Also, that there be a social service in connection with the clinics

The problem of tuberculosis is indicated in the 886 deaths. There are available 573 beds for indigent cases, there is no satisfactory provision for the institutional care of tuberculous children, no preventorium care, no open-air schools as part of the school system. The need for 350 additional beds for tuberculous indigents is pointed out, and the need for provision for institutional care of children, of preventoria, etc

It is recommended that the Department of Health provide a diagnostic service in the home, upon the request of attending physicians, for cases unable to attend at one of the tuberculosis institutes

Montreal's maternal mortality rate of 3.8 is comparatively satisfactory. Considerable work

is being done in this field, and the results are evident. Thirty-five per cent of the city's ante-natal cases have some ante-natal home nursing supervision, 13 per cent were under clinic supervision. The Victorian Order of Nurses attended 77 per cent of births, the Royal Victoria Montreal Maternity Hospital and L'Assistance Maternelle, 36 per cent of births occurring at home. The report states that, considering housing conditions, more than 16 per cent of births should occur in hospital. The need for further development of existing services and for the registration and supervision of licensed midwives is stressed. At present, midwives are licensed by the College of Physicians and Surgeons, but there is no local registration of those practising, and no supervision. (This is not an endorsement of midwives, but it is thought that as long as they are licensed, they should be supervised.)

The infant mortality rate in 1927 was 113, the rate for French-Canadians, 144, British-Canadians, 55, Jews, 26. It is recommended that, working in and from every well-baby conference, there shall be at least one graduate registered nurse. The lack of such personnel handicaps the infant welfare work, which is extensive, though varying greatly in quality.

An extensive review of the system of School Medical Inspection Service is presented. The school population is 126,000. There is no dental service. It is recommended that such a service be organized and a staff of 20 dentists, with a similar number of dental assistants be provided.

The need in Montreal for special classes is estimated as provision for

2,200 children in classes for mentally-handicapped, 1,260 children in open-air classes, 500 children in summer open-air schools (Forest Schools), 250 children in sight-conservation classes, 125 children in crippled children's schools.

Based upon the number of individuals who are to be served, the estimation being made upon the number of cases of communicable disease, tuberculosis, venereal disease, the number of births, the school registration, etc., it is estimated that Montreal requires 184 public health nurses (not including bed-side nursing service), and of this number, 132 should be on the staff of the Department of Health. On May 1st, the Department had 46 public health nurses. Some eighteen recommendations are made as to public health nursing, covering the needs of this important service.

Programs for Industrial and Mental Hygiene are presented. The need for amendments to the Housing By-Law are detailed. It is recommended that 50 additional neighbourhood playgrounds be provided. The situation regarding Cancer and Heart Disease is described, and certain recommendations are made, including a free pathological diagnostic service for cancer, the follow-up of communicable diseases to urge supervision by the family physician, the provision for adequate convalescent care and popular health instruction.

Chapters are devoted to a consideration of the Milk and Food Supplies and Popular Health Education.

The Report concludes with a suggested budget for the Department of Health, based upon the recommendations made, proposed by the Committee as a three-year program.

The expenditure in 1927 was \$274,201.58, the recommended budget is \$638,640.00, which is 91 cents per capita on the basis of a population of 699,500.

HEALTH DISTRICTS*

By M. M. SEYMOUR, M.D.,

Regina

Saskatchewan was created a province in 1905, but used the North West Council Ordinance passed in 1902 for health matters until the enactment of the Public Health Act in 1909 which provided for the establishment of a Bureau of Public Health.

In 1923 the Department of Public Health was created, and in 1927 was amended, making provision for the formation of Health Districts.

In the two largest cities of the province there is a full time medical health officer, who is assisted by such technical help as the size of the city calls for and its council can be persuaded to provide. In the smaller cities the medical health officer is a local practising physician, who gives more or less of his time to public health for little or no pay. As a rule, the part time medical health officer has no training in public health except that which he acquires by experience. Often he loses practice in communicable diseases because people find that they are shut in by the medical health officer but may escape if seen by another doctor. All these factors, poor pay, want of co-operation, lack of education of public opinion, scanty funds, contribute to render part-time medical health service of little value to the community. Places that have a full time medical health officer develop a useful organization.

By an amendment, which was assented to March 7th, 1928, the Saskatchewan Legislature enacted that the minister may prepare a scheme for the organization of Health Districts, consisting of a number of municipalities, and may submit the same for the approval of their respective councils. The amendment goes on to say that there shall be not less than eight rural municipalities in a district, and towns with a population of less than 10,000 shall be included. The scheme shall provide for the appointment of

* Summary of an address by Dr. M. M. Seymour, former Deputy Minister of Public Health, Saskatchewan, now Special Adviser on Public Health to the Saskatchewan Government, delivered at the Regina and District Medical Society, September 5, 1928.

a medical and sanitary staff, consisting of a qualified medical practitioner, one or more sanitary inspectors, one or more trained nurses, and a secretary, who shall devote their whole time to the health and sanitation of the district. The scheme shall give an estimate of the expense involved and shall state that one-half the expense is to be borne by the municipalities. The minister shall submit the scheme to the councils of the various municipalities for their approval, the councils shall consider it and approve or disapprove at the first regular meeting held after the receipt of the scheme from the Minister.

The cost for the District will be \$14,000 a year. Fifty per cent of this is to be paid by the rural municipalities, towns, and villages in the district, 25 per cent will be paid by the Department of Public Health, Saskatchewan, which also makes all appointments, directs and controls the work, 25 per cent will be paid by the Rockefeller Foundation, which will also pay for special training given to the personnel. The average cost per capita will be 35 cents.

The Health Unit will control communicable diseases, improve sanitary conditions, regularly inspect school children, make recommendations for the correction of defects, consult with teachers on all matters pertaining to personal hygiene and personal health, stimulate interest among adults in periodic health examinations, arrange for vaccination and immunization of school children and others, conduct clinics for pre-school children, hold pre-natal clinics and public health meetings, visit the homes and give instruction there.

The use of the laboratory will be made available without charge to local practitioners.

The district of Assiniboia is to have one of the first Units. In 1926 there were 187 deaths in this district, study of the mortality returns show that 119 of these deaths were from preventable causes. Four hundred and twenty persons were sick each day of the year in the district.

In 1926 there were three hundred and eighty-two deaths reported from tuberculosis. Authorities say that for every death from tuberculosis there are from five to ten cases left behind infected with the disease in a communicable state. Saskatchewan has 600 beds for the care of tuberculosis. Multiplying the number of deaths mentioned above by the lower figure, namely, five, we have 1,910, and 600 beds for 1,910 leaves 1,310 cases of tuberculosis in the communicable state in the homes of Saskatchewan. The personnel of the Health Unit will be made aware of where the homes in the district are from which the patients have gone to the Sanatorium. Inmates of these homes will be carefully examined by the physician who will give advice as to how the sick ones should care for them-

selves and how they can take precautions to prevent communicating the disease.

Heart disease and its prevention will be another interest of the Unit.

Denmark, Sweden, Italy, and Switzerland have maternal mortality rates of between two and three per thousand, Canada has an average of between six and seven per thousand.

Immigration from other countries is receiving much attention, yet 26,000 of our own newcomers, that is babies born in Canada, die every year before they are twelve months old.

The Health Units are designed to promote the conservation of that most valuable possession, human life.

THE WORKMEN'S COMPENSATION ACT OF THE PROVINCE OF QUEBEC

By F. J. TEES, M.C., B.A., M.D.,

Montreal

To the Province of Quebec belongs the credit of being among the pioneers in workmen's compensation legislation, the Act of 1909 being one of the first of its kind. Recognizing however that many of the provisions of the original Act had become obsolete, the provincial legislation, after unhurried consideration, recently introduced a completely revised measure which became effective on the first day of September, 1928.

By the new Act a Commission of three is established, with full jurisdiction to interpret and administer. This supersedes litigation in the Courts with its associated delays and other undesirable features, prominent among which has been the evidence given in the witness-box by medical "experts," frequently conflicting, oftentimes detracting from the dignity of the profession.

Indemnities for permanent total incapacity, for permanent partial incapacity and for temporary total incapacity, have all been materially increased, in the event of death, a "rente" equal to 30 per cent of the yearly wages is granted to the widow, with an additional allowance of 10 per cent for each child (30 per cent maximum) under the age of sixteen.

The injured person is entitled to all medical, surgical, pharmaceutical and hospital charges, (according to a tariff which has been approved by the Lieutenant-Governor-in-Council), as well as to transportation to the nearest hospital. Where there is more than one hospital, the injured person may select one of his own choice.

The clause relating to the choice of medical attendant reads as follows: "The employer must procure for the injured person whose mother tongue is French or English, the services of a

physician, and, if required, of nurses speaking his language."

To guarantee the payment of indemnities and expenses the employer is obliged to obtain insurance with an insurance company approved of by the Commission. Provision is made, however, at the discretion of the Commission, for certain companies to act as self-insurers, adequate guarantees being demanded.

Notice of an accident must be given to the employer by the injured within ten days. In the case of an accident entailing incapacity for more than seven days, the employer is required to notify the Commission within fifteen days. Many minor accidents will accordingly not become the concern of the Commission. If the incapacity lasts less than seven days the injured person is still entitled to medical attendance. Payments for temporary total incapacity at the rate of two-thirds of the daily wages begin only on the eighth day after the accident unless the incapacity exceeds six weeks in which case the first week will be compensated for.

A schedule has been prepared indicating degrees of permanent partial incapacity in re-

spect to certain injuries. In cases not provided for in the schedule this is intended to serve as a guide, taking into account "the injured person's capacity to continue the same kind of work as he was doing before the accident or to take up another kind of occupation."

With so many interests touched by legislation of this kind—those of the employer, the employee, the insuring companies, the medical and legal professions—it is not to be wondered at that differences of opinion should arise concerning certain minor details of the Act, but the new enactment is recommended to the study of those interested in industrial medicine as a constructive measure. There are those, who, having given much study to corresponding acts in various countries, believe that the Quebec Workmen's Compensation Act of 1928 embodies legislation that for fairness and practicability leaves little to be desired. The members of the medical profession of the Province are recommended to familiarize themselves with the details of the Act and to give a full measure of support to the Commission in the onerous task which they have assumed.

Men and Books

AN EARLY CANADIAN BIOLOGIST— MICHEL SARRAZIN (1659-1735) HIS LIFE AND TIMES*

By MAUDE E. ABBOTT, B.A., M.D.,
Montreal

The *David Prize* for the best essay on Canadian history was awarded for the year 1926 to Dr. Arthur Vallée of Quebec, for a brilliant biographical and historical study bearing the above title. Published in the following year, 1927, by the King's Printer, as one of the series of the *Quebec Archives*, this work forms a neatly bound volume of 299 pages, of which 220 are occupied by the monograph itself and the remainder by an appendix containing a selection from the original documents on which it is based (*Pièces justificatives*), the latter forming not the least valuable part of a very important publication.

The appearance of this book is a real event, not only in Canadian medicine itself, but in the history of medicine on this continent as a whole,

for it covers a period in which civilization was successfully replacing barbarism throughout all the then known parts of North America, and it unfolds a chapter from the history of this time that until now has been but too little understood and quite inadequately portrayed. As its title implies, this book not only rescues from partial oblivion the name of an illustrious pioneer in medicine and biological research, whose achievements were well abreast of those of any of his contemporaries in these fields on this side of the Atlantic, it also presents a clearly defined picture of the practice of medicine in contemporary French Canada, in what is now the Province of Quebec, during the latter part of the 17th and early 18th centuries, some one hundred and fifty years after its first settlement. In this district, amid a scattered population that numbered at this time about 15,000 souls, nurtured under the ministry of the Catholic Church and her devoted sisterhoods, but unprotected as yet by the Act of Registration of 1788, a great variety of practitioners, regular and irregular, flourished. Among them were a few qualified barber-surgeons with experience gained in France, and then apprentices, as well as other persons of honest purpose, locally trained or self-educated, whose scanty knowledge was eked out by their gift of commonsense, as well as midwives trained in France or practising untrained. To these were added a host of

* *Un biologiste Canadien, Michel Sarrazin (1659-1735) Sa vie, ses travaux, et son temps*. Par Arthur Vallée, Professeur à l'Université de Laval. *Prix de Concours de l'Histoire de Canada, 1926 Archives de Québec*. Imprimé par L. S. Proulx, Imprimeur du Roi, Québec 1927, viii, 291 pages. Published also by La Librairie Garneau, paper cover.

charlatans, whose trade thrived upon the credulity of the people and the quaint beliefs and customs of the time. Among this heterogeneous crowd of worthy and unworthy followers of his art, the name of Michel Sarrazin, physician-in-chief of the King to the hospitals of New France, student of the *École de Médecine* of Paris, and Doctor of Medicine of the University of Rheims, Corresponding Member of the *Académie Royale des Sciences*, contributor to its *Transactions* of original dissertations on the anatomy and physiology of animals indigenous to Canada, and donor to the *Jardin Royal* of Paris of living specimens of practically the entire Canadian flora of his vicinity, stands out pre-eminent, as does that of his great successor in the next generation, Jean-Théophile Gauthier.

Dr Vallée explains in his introduction that, in order to depict the figure of this ardent research worker and foremost physician of his generation from the scanty material available, he has considered it essential to reconstruct as far as possible his environment, and to recall the status of the art and science of medicine at that time, both in Old and New France, as well as the more important personnel of the medical confraternity by whom he was surrounded during his fifty years of active professional life at Quebec and Montreal. For this purpose, as well as for that of the biography itself, he has made a careful research in the Dominion and Provincial Archives, in the Paris offices and libraries, and in the *Bulletin des Recherches Historiques* and elsewhere, for documentary evidence of all sorts, reference to which is shown throughout the book by footnote or annotation. The time has passed, he writes, for the birth and origin of Canadian history to rest on legendary tales or unsupported tradition. The occasion has arrived for the scientific presentment of historical facts based only on actual documents and on those precious but all too scanty records of old families and their dependencies which constitute the true background of the Old Régime in Canada. Unfortunately, apart from the Public Archives, little remains of a personal nature that could initiate us into the private life of Sarrazin, or reveal anything of his physique or character. Apart from his scientific publications, all that we have to go upon of a personal nature are several letters, thirteen in number, dealing with his administrative functions or scientific work, discovered at the *Académie des Sciences*, the *Bibliothèque de Rheims*, the *Seminaire de Quebec*, and the *Bibliothèque Nationale*. All the more necessary has it been, therefore to review the few data that we have of his life in the social, political, religious, scientific industrial and commercial setting of his time and place, where we can see him in his true values in very close proximity to those great names who in that era built the history of New

France. "Here it is that we have tried to retrace Michel Sarrazin de l'Etang."

The Foreword closes with an appeal to his French compatriots to be worthy of the high tradition that is unfolded to them in this book and to follow Sarrazin in making a definite contribution from French Canadian medicine to the science of the world. It may well be transcribed here:

"Car à côté des gloires militaires et politiques, ecclésiastiques et sociales, il reste le prototype de la science des premiers jours, et peut être de toujours à date, au pays de Québec. Or la science fait partie de l'histoire du monde. Au même titre que les arts et les lettres, elle a sa place dans la suite des temps. Et nous voudrions en citant Sarrazin aux générations montantes, provoquer dans les esprits la réaction nécessaire à l'éveil scientifique national. L'homme qui dans son lourd labeur a voulu porter une attention spéciale aux deux éléments qui devaient plus tard constituer notre emblème le castor et l'érable, semble bien mériter qu'on se souvienne de lui. Nul ne peut à plus juste titre devenir le guide de ceux là que, suivant son exemple reprendront le sentier tracé pour fournir à leur tour l'apport de la science canadienne française à la science mondiale."

Who then was Michel Sarrazin, and what were his contributions to the science and life of his time? And what insight does Dr Vallée's book give us into the practice of medicine in this country before the English conquest of 1760?

A reply may best be given by tracing briefly below the thread of Dr Vallée's narrative. It must be understood, however, that in order to do justice to this subject the book itself must be read and studied by all those interested. For it is a classic in its line, as concise and authoritative as it is romantic and informing, and is moreover a pioneer achievement in a virgin field—the first authentic history of medicine in French Canada.

I THE COLONY AT THE END OF THE SEVENTEENTH CENTURY

ORIGIN OF MICHEL SARRAZIN

Michel Sarrazin was born on September 5, 1659, at Nuits-sous-Beaune in Burgundy, the son of Claude Sarrazin, bailiff of the estates of the Abbaye des Cîteaux and of Madeleine de Bonnefon his wife. These names are met with some two centuries earlier in Upper Burgundy, the country of Buffon and Daubenton. He arrived at Quebec in the summer of 1685, at the age of 26, bearing the title of surgeon, on a ship carrying a marine detachment (so-called after the ministry that despatched them). He thus formed a part of the large immigration to Canada of the sturdy Burgundian race that began in 1675 and permeated the colony in the early 18th century. Another surgeon of the same origin Jacques Desquay, preceded him by thirteen years and settled at Three Rivers. Sarrazin's arrival in Quebec coincided with that of the Abbé de St Valier and the Intendant Denon-

ville, and it is probable that his services were immediately called upon in the epidemic that broke out among the accompanying regiment, and for other exigencies of the colony, for the following year, September 12, 1691, he was appointed by the Conseil Supérieur, Surgeon-major to the troops in Canada. This was ratified by royal mandate from Versailles five years later in the following terms

"Aujourd'hui 16 mars 1691 le Roy estant à Versailles voulant commettre une personne capable et expérimentée au fait de la chirurgie pour traiter et panser les soldats des troupes qu'Elle entretient au pays du Canada, et sachant que le Sr Sarrazin a les qualités nécessaires pour s'en bien acquitter, Sa Majesté l'a retenu et ordonné, retient et ordonne chirurgien des troupes qu'Elle entretient au dit pays aux appointemens qui luy seront ordonnez par les estats qui sont expédiés chaque année pour l'entretien des dites troupes et autres dépenses à faire au dit pays pour le service de Sa Majesté Mandé au Sr Comte de Frontenac, etc."

The colony at the time of Sarrazin's first sojourn in Canada (1685-1694) could no longer be considered uncivilized, but it rather mirrored in spite of material difficulties, the life of the period in the Provinces of Old France. The population was already divided into parishes with larger centres at Quebec, Montreal and Three Rivers, and to these was coming an incessant influx of colonists of high as well as low degree. Law and order was maintained by the institution of the *Conseil Souverain de Québec* (later the *Conseil Supérieur*), which enforced the edicts and ordinances of the French rule and judged the difficulties of the community as they arose. This Council, formed as it was of the élite of the country, and numbering on its roll all the great names of the colony, constituted a local aristocracy of high repute. The clerical administration was organized on a peculiarly liberal basis for that epoch, with secular and regular clergy, while education was cared for by primary schools, a preparatory Seminary and Jesuit College at Quebec and the Sulpicians and others at Montreal. In spite of monopolies, commerce and industry, under the recent wise administration of the patriotic Intendant Talon, were flourishing, and to the fur trade, lumber and fishing export, were added grist mills, tanneries, etc., for home manufacture of the necessities of life. The Hôtel Dieu de Québec, founded by the Augustinian nuns in 1639, had become in 1690 a well-organized hospital of some fifty beds, containing a ward for men and another for women, with a place reserved for the care of sick officers and a Hôpital Général, caring especially for the mentally afflicted, had also been opened. Among the practitioners who had come as "medical colonists," or from an interest in the fur trade or other reasons, are mentioned especially at this time Duchesne, a surgeon whose name is attached to medico-legal reports of the time, and who became proprietor of the later Plains of Abraham, Giffard, first physician to

the Hôtel Dieu of Quebec, who received the Seigneurie of Beauport in acknowledgement of innumerable services, and who was the first Canadian habitant to receive letters patent of nobility, and Jean Madry the noted barber-surgeon, the first alderman of Quebec, who succeeded Giffard at the Hôtel Dieu, and first established the practice of surgery in the colony, and, as of some prestige also, Timothy Roussel and Beaudoin. "To these, *médecins colons*, and many others less in the limelight, came Michel Sarrazin to lend the strong hand of his fellowship and support. Like them, conscious of duties beyond the bounds of his profession, he mingled with the entire local life. More than any of these he was to shed lustre upon Canadian science at its dawn, and on the medicine of this time. But, with perhaps a wider horizon, he remains of the same race and type. A brave man who knows how to do hard labour, a pioneer such as France has always known how to supply to the entire universe, carrying everywhere his faith, his science and his initiative."

Of Sarrazin's actual professional activities during this early period of his life we know relatively little. His name occurs as surgeon attending several duels, and from his military appointment he was certainly active among the wounded during the siege of Quebec by Sir William Phipps in 1690. In 1693, also, he was appointed physician to the Hôtel Dieu by the Sisters, who held him in high esteem, and he undoubtedly practised his art, not only among the troops but throughout the colony, where under arduous conditions of travel he is said to have given gratuitous surgical aid within a radius of sixty leagues. On one of his visits to Montreal in the year 1692, he fell seriously ill and made a notarial will dated at the Hôtel Dieu and preserved in the City Archives, in which he bequeathed his surgical books to three local surgeons, the Sieurs St Amand, La Source and La Sonde, who had evidently attended him. The bequest was revoked later in a second will made during a subsequent illness of his at Quebec.

But the most interesting document extant relating to him at this time is a "*Mémoire des Médicaments nécessaires pour les Troupes du Roy au Canada pour envoyer en 1693*," which is published here in the Appendix. It is, as Dr Vallée remarks, a perfect example of the polypharmacy of the day, being headed by the Theriacum of the middle ages (said to contain over ninety ingredients and containing also a rich supply of essential oils, syrups, ointments, plasters, extracts and drugs of all kinds, including the much disputed antimony), as well as "2 dozen lancets for bleeding," syringes and cauteries for wounds, and other implements of the surgeon's armamentarium. Comparison of this list with that drawn up by Jackson the surgeon in charge of Phipp's forces is said to

have shown a very similar content in the English one

Little or no evidence appears at this period of the profound interest in natural history and the scientific trend which were so prominent a feature of Sarrazin's later life. Two facts only are significant of this. His intimate friendship with Franquelin, the hydrographer of the Jesuit College, and the dissatisfaction which he felt at the inadequacy of his training as a barber surgeon, led him, after eight years' practice in this country, to resign his military office and return to France for the purpose of obtaining further medical training and a university degree. The surgeon Beaudou was appointed by Frontenac in charge of the troops in his place in 1693, and in 1694 Sarrazin sailed for France, to return to Canada three years later with the desired academic qualification, a trained scientist with connections established among the leaders in his field of research, and to become, in deed as well as in name, the foremost physician of New France and an important factor in her rapidly expanding national life.

II MEDICINE IN THE SEVENTEENTH CENTURY SARRAZIN'S SOJOURN IN FRANCE (1694-1697)

There was apparently at this time some question of his entering the church, but his heart was evidently set upon his original vocation, and almost immediately after reaching Paris he seems to have entered upon his studies at the *Ecole de Médecine*, where he followed lectures at the amphitheatre Riolan, and received clinical instruction at the *Hôtel Dieu de Paris*. The degree of Doctor of Medicine, for which he had enrolled himself, called for a preliminary Master of Arts diploma, and a seven years' course of study, and that he was able to abridge these requirements within the three years of his stay in France is probably to be explained by the wide clinical experience which he had gained in practice in Canada. He presented himself in due course in 1697 for the Doctor's degree at the University of Rheims, from which some thirty years later his son also graduated.

It is difficult at the present day to realize the great distinction that existed in Europe and particularly in France at this time between the *physician* and the *surgeon*. The latter's work was not considered so much an *art* as a *trade* for which no long preparation was necessary, and this was usually acquired in the provinces. As already intimated, practically all the qualified practitioners in New France were of this type of barber-surgeons, and it is little wonder that a man of Sarrazin's intellect and humane feeling should have felt the urge for wider knowledge for his treatment of the sick. To understand the tremendous intellectual im-

petus which a university training in Paris at that time must have brought to this mature student, whose mind had been sharpened by hard won experience, one must recall the real status of medicine itself at this time. The seventeenth century was, as is known to us all, a classic age. It opened with Harvey's discovery of the circulation of the blood, which gave the impetus to other researches in physiology already bearing fruit, chemistry and physics were, under the guise of mistaken mechanistic theories, still in course of development, and the great anatomists, such as Morgagni and Malpighi, were opening the door to modern conceptions of the structural changes in disease, while at the same time the English clinician Sydenham, who died in 1689, had, by his power of observation and method of delineation of certain disease entities and their rational treatment, brought these new found principles to a focus in the birth of the great science of clinical medicine. The *Ecole de Médecine* was itself full of discussion and eager disputation of these new ideas that were trembling in the air. Moreover, this Paris, under Louis XIV, was actively fostering two other great scientific movements, allied to medicine and ministering indirectly to its advancement, both of which became to Michel Sarrazin an avenue and a source of inspiration for his future work. These were the *Jardin des Plantes*, and the *Académie Royale des Sciences*.

The *Jardin Royale* or *Jardin des Plantes* (which became after the Revolution the Museum of Natural History of Paris) was founded in the reign of Louis XIII by two "médecins du Roi" Herouard and Gui de la Brosse, and was not entirely unconnected with medical teaching, for in its deed of incorporation it was stated that since at the *Ecole de Médecine* the operations of pharmacy were not taught, it had been requested by the *Sieur Bouvard* that "three doctors chosen from the Faculty of Paris should be appointed to demonstrate to the students the interior of plants and all forms of medicines and to work on the composition of all kinds of drugs." How far this was carried out does not concern us, but under Louis XIV, Fagon, médecin du roi and director of the *Jardin*, a nephew of Gui de la Brosse and deeply interested in natural history, appointed from the province Joseph Pitton de Tournefort to be Professor of Botany at the *Jardin*. This de Tournefort, known as the great precursor of Linnaeus, is said to have founded the modern science of botany, and he it was who created the Museum of the *Jardin*, both from collections made in his own travels and from the fruits of the travels of others. Curiously enough, though a professor of botany, he was a fellow student in medicine of Sarrazin and sent in his thesis for the degree a year after the latter, in 1698,

and he became Sarrazin's earliest protector and his first link with the scientific world

The Académie Royale des Sciences was the outcome in the middle of the seventeenth century of intimate reunions of the best minds of Paris, among whom are mentioned the Descartes and the Pascals. It was founded in 1666 by Colbert, but was reorganized and regularly constituted by Louis XIV in 1699. Here were assembled the great men of the period, represented in their respective fields by such names as Tournefort, Réaumur, de Fontenelle, Boerhaave, Roemer, Peter the Great, Mariotte, Malebranche, and Sir Isaac Newton. These and such as these were opening the way for the new thought and advances of to-day, and they went about their work of preparation for the centuries to come with a precision of which we are far too often ignorant. Above all, they sought to widen the field of knowledge by the utilization of all the sources of information accessible to them, both by sending forth their members to distant parts, and by entering into correspondence with carefully selected persons in foreign places, realizing that science has no country and that relations between research workers must be world wide in scope. Sarrazin was made such a corresponding member, selected by de Tournefort on March 4, 1699, at the same meeting at which Sir Isaac Newton was elected an "associé étranger."

III RETURN TO CANADA SARRAZIN AS PHYSICIAN-SURGEON IN NEW FRANCE (1697-1735)

Dr Sarrazin's return to the colony after his three years' absence in Europe was probably hastened, rather against his will, by urgent appeals from the people and from the Intendant for the return of this man who "having acquired consummate knowledge of surgery during six or seven years in this country has gone to France to complete his perfecting in the study of medicine" (extract from letter from Champigny to the ministry dated November 6, 1695, soliciting his recall at a salary of 600 livres). It is quite clear from documents in the Quebec Archives that he came back with the definite intention of devoting at least a part of his time to the scientific interests he had developed in Paris and to utilize his distant location for the dissection of rare animals and researches into unknown plants, and not entirely to the treatment of the sick. That he continued to carry out this resolution in full measure in the midst of an enormous and most engrossing practice was not the least remarkable feat of his crowded life. Even before his landing he was plunged into the vortex of professional responsibility and activity, for a serious epidemic of hæmorrhagic "purpura" (*i.e.*, typhus fever) so common under the cold and dampness and the complete lack of sanitation and inadequate food

supply that prevailed on shipboard in those days, broke out on the vessel on which he sailed, and spread from it to the habitants of Quebec and to the Religious of the Hôtel Dieu, which was deluged with patients. Sarrazin threw himself into the necessities of the situation with complete devotion and with apparently extraordinary success, for practically all those affected on board were said to have recovered from a malady which twelve years before had carried off more than eight hundred victims! In the face of his already high reputation, the inevitable result was that he was besieged on all sides by individual patients and by requests for consultations from practitioners and cures, and in the year 1700 he was appointed by Royal mandate, and on a salaried basis, Médecin du Roi and Physician to all the Hospitals of New France, with a vast clientèle that stretched from Quebec and Three Rivers to Montreal, and *ex officio* chief medical attendant upon the Governor of the Colony, Monseigneur de Laval, de St. Valer, and all other notables.

In this same year 1700, another epidemic, this time of "la grippe," broke out, and was followed during the winter of 1702 by the terrible scourge of smallpox, which, starting from a house in which a passing Indian had died of the disease, spread like wildfire through the city, with such a multitude of fatalities that individual burial could not be carried out and fourteen to eighteen bodies were committed daily in a single grave, to the number of some two thousand. The same dread disease visited the city in 1703, and the "Mal de Siam" (yellow fever), which had appeared sporadically from time to time, assumed the proportions of an epidemic in 1709. Tuberculosis was apparently indigenous and so attracted the concern of Sarrazin that he sent a request to France, which was promptly granted, for asses to supply the milk then recommended for these patients. Added to these infections were those maladies dependent on the severe climatic conditions, rheumatism and lung diseases, and the scurvy still attended the poverty of diet that often prevailed.

In the domain of general medicine Sarrazin was no less successful than in these more specific fields. He cured M. de Callières, at least temporarily, of a dropsy, and his treatment of pleurisy by alternate diaphoresis and bleeding, which was written out by him in manuscript, was employed with success by M. de la Galissonnière (as recorded by Kalm), and is an excellent illustration of his therapeutic method. He used Glauber's salts in huge doses, and was officially employed by the ministry to investigate, with the apothecary of the Jesuits' College, the chemical composition of this salt. His botanical work again helped him to greatly enlarge his practical knowledge of local remedies and he never fails to note in his description of

every plant which he gathered and studied, its pharmaceutical properties and the native uses to which it was put. The remarkable catalogue of two hundred living Canadian plants, presented by him to the Jardin des Plantes in 1704, reproduced in facsimile in the appendix of this book, abounds in such annotations. Some were noted to have diuretic properties, others were emetics or purgatives and, as in the case of the *Aster corona*, of use in epilepsy or convulsions, others, as the *Aralia canadense*, valuable for the treatment of anasarca, others were used by the Iroquois to neutralize snake bite, still another as an abortifacient. Throughout, however, he maintains his critical judgment, rejecting certain substances, as a certain bark for the cure of cancer, after due experimentation, as of unproved efficacy.

Nor did he in the exercise of his new profession lay aside the art of surgery which he had practised so successfully before his return to France. The annals of the Hôtel Dieu of Quebec contain many records of wounds dressed and operations performed by him in this later period of his life. Of these the most interesting is the account of his treatment of the Mother Superior of the Congregationists in Montreal, who suffered from an intractable cancer of the breast, the result it is said of the irritative action of penitential girdles, and who came to Quebec for operation by him about the year 1720. After treating the field of operation for some ten days, and partaking of the Holy Sacrament with his patient and the entire community of the Hôtel Dieu, he proceeded to the amputation of the diseased organ, with complete success, for the reverend patient made a good recovery and lived in the full discharge of her activities for nineteen years longer, dying at the age of seventy-nine. Another operation of the same sort was performed by him on another nun a few months later.

On Dr Sarrazin's activities in medico-legal questions we have not space here to dwell. Such enquiries were carried out regularly and efficiently, in small as well as large matters, under the Criminal Act of Louis XIV, and he was often called upon to officiate, as in an enquiry instituted on October 23, 1702 upon the cadaver of one La Chaume, assassinated.

Among the fellow practitioners who flourished in New France during this later period of Dr Sarrazin's life are mentioned especially Berthier who was also a salaried *medecin du roi* and assisted him in his attendance on the Governor, and was a surgeon at the Hôtel Dieu until 1725. Timothy Roussel, physician to the Hôtel Dieu, whose offices were in the rue de la Buade, where he built the famous house of the Chien d'Or. Benoit, surgeon to the hospital at Montreal with his son, born in the country, and educated only by local studies, and the Soupérans who

practised at Quebec through three generations with no other knowledge than what had passed from father to son. In a class by themselves were the Fières Boispineau, apothecaries at the Jesuit College, who openly practised medicine for many years with much success. Madeleine Bouchette, a trained midwife, who came out on salary from the king in 1722, represented another group, as did David and Gaschet, apprentices of Timothy Roussel. Among the most famous of the actual charlatans of the day were Marguerite Désy of Three Rivers, as celebrated for her cures as for her scandalous conduct, Phlem, who came out as a healer from France, and François Paris dit La Magdaleine and his wife. Considerable protest was made against this unchecked liberty of practice before the Act of 1788. Thus Lajus, physician to the Hôpital Général in 1712 petitioned the Conseil to limit the number of surgeons in Quebec to four, and to impose a fine of two hundred livres, with confiscation of all his drugs and instruments, on any surgeon from abroad setting up practice there, and Timothy Sylvain (Sullivan), of Irish extraction, was required by Governor de Beauharnois to pass an examination on his medical knowledge before Dr Sarrazin, the only person in the country competent to judge of his fitness.

IV and V A MEMBER OF THE ACADEMIE ROYALE DES SCIENCES SARRAZIN AS BOTANIST AND BIOLOGIST

At one of the first meetings of the Academy after its reorganization early in 1699, "all the Academicians present named different persons with whom they would be in correspondence on their respective sciences, either in the provinces or in foreign countries," and de Tournefort at this time designated Dr Sarrazin to be his Corresponding Member. He remained in this relation until de Tournefort's death in 1707, and made most of his botanical communications as well as his donations to the Jardin des Plantes, through the latter. Later, he presented them through the Abbé Bignon, until in 1717 he was again selected by the great scientist Réaumur to be his Correspondent, and from then on date most of his remarkable contributions on the anatomy and physiology of the native Canadian animals.

Sarrazin was thus only one of a large group of research workers scattered throughout the Antipodes, whose powers were being taxed along the same lines, and both missionaries and explorers had faithfully endeavoured to describe, and as far as possible classify, the new forms of plants and animal life. Considerably before his time too, both beaver and muskrat and their habits had been portrayed. Thus Dierreville had published at Paris in 1635 a *Canadensium plantarum*

history, and Pierre Bouchei, Governor of Thiee Riveis in 1665, wrote a *Histoire naturelle de la Nouvelle France, vulgairement dit Canada*, while an eighteenth century book bears the title *Traité des animaux a quatre pattes terrestres et amphibies qui se trouvent dans les Indes Occidentales*, followed by a *Traite des oyseaux*, and a *Traité des poissons*. It is, however, very interesting to note, writes Dr Vallée, that he stands in the forefront of these workers by virtue of his methods, both of observation and approach, which are those of modern biology. "An incomparable anatomist, whose descriptions were not to be surpassed, he pushes this study to the finer structure of the tissues and organs, to a point that might be controlled without fear of error by the microscope. A physiologist in embryo, he does not stop at the gross findings of the great animal functions but dives without hesitation into the most complex mechanisms that form the field of biological researches to-day. Employing hypothesis with discretion, he insists upon an absolute control of all his observations, and confirms by repeated examination of the same object under varying conditions the findings which he believed he had made in his first research."

"Moreover he had the passion of the research worker revealed in all his correspondence and all his intimacies, in his initiative and his power of overcoming difficulties and associating others with him for purposes of verifying and controlling his original findings. In all these ways he revealed himself a consummate man of science."

His actual scientific contributions can be only briefly enumerated here. In botany there stands first of all his great contribution to the Jardin Royale of living specimens of practically all the Canadian flora, which remained alive there ten years after their donation, with a descriptive catalogue which is reproduced in facsimile in the Appendix. It is said that he himself transplanted and watched over each of these plants as he studied them, and forwarded descriptive memoranda upon them with written instructions as to their care and directions to collect the seed and return it to him.

Of his original descriptions of plants not previously known, the most important treats of the "Pitcher Plant," which grows throughout America and was called by Tournefort after him the *Sarracena purpurea*, its botanical name to-day. His description of it is given with the same luxury of detail that characterizes his contributions on animal anatomy. It is published in full here and should be read.

A later botanical contribution of his that touches on a subject of national importance is that published in 1730 in the *Mémoires de l'Académie* on the "Sugar Maple." He describes four varieties in the country, notably

"*L'Acer canadense sacchariferum fructu minore*," and states that the French, following the Indians, know the sugary character of its sap in springtime, the climatic conditions favourable for a good running (snow, thaw, frost), and how much sugar a tree three or four feet round will give in a season. Competent authorities give him the credit, if not for the discovery, at least for the industrialization, of maple sugar. A specimen of the sugar maple was included in his large donation of plants to the Jardin in 1704. The "Blueberry" is another common Canadian fruit which Sarrazin made known in France.

An outcome of his insight into plant life significant of his truly extraordinary sagacity and foresight in the application of natural laws, is a fact told us elsewhere in this book (page 146-146), when dealing with his activities for the civic welfare. As a member of the Conseil Supérieur he had been asked to look into the question of harvesting and sowing grain, a vital question then, as now, in a country with short seasons, and Dr Vallée quotes from Kalm that "Dr Sarrazin had procured in Sweden a small quantity of winter wheat and barley. This was sown (by him) in autumn, passed the winter without damage, and produced fine wheat the following summer, with grains a little smaller than the wheat of Canada."

"but this winter grain gave a larger amount of fine flour than the summer wheat. *I have never been able to understand (wrote Kalm) why this experience was not continued*." In view of the modern transformation in the harvest acreage of Canada through the introduction of wheat adapted to a short summer, this practical application at that date of Sarrazin's scientific intelligence is truly astounding.

Sarrazin's first personal observations on the beaver appeared in the Transactions of the Académie Royale for 1704, (through de Tournefort) and reports a minute dissection of an animal weighing fifty pounds. As a model of his fine anatomical style his classic description of the muscles of the back and of their fasciae and aponeuroses is given verbatim, and is so clear that, as his biographer says, one can reconstruct from it the whole lateral wall. From the functional standpoint his greatest interest centres upon the formation and minute structure of the generative organs, and here he made the curious discovery of a single cloaca, making the distinction of the sexes in the beaver difficult. His most masterly exposition, however, is given of the digestive tract and its linings, and he describes also the false ribs possessed by this animal. Twenty-eight years later he returned to this subject and sought other beavers for dissection, to confirm and extend his earliest observations.

Sarrazin's masterpiece in zoology was how

ever presented in 1725 through Réaumur, and is entitled "An extract of Various Memours of Monsieur Sarrazin on the Muskrat." It is illustrated by sixteen different figures made by himself (failing another draughtsman). The description of the stomach and the changes that take place in it during digestion and on summer and winter diet is a classic, and in view of his limitation to a "loupe," or some elementary form of microscope, is a real *tour de force*. He described also the carcajon, the "vache marine," "loup-marin," and in great detail the porcupine describing in the latter animal seven different kinds of skin and discussing at great length the question as to whether it throws its spines when attacked, as usual he delays upon the subject of the genitalia in which he finds a number of small peculiarities. He even attempted to dissect a skunk, but gave it up "because it had a dreadful smell, capable of making a whole canton desert."

VI SARRAZIN IN SOCIAL AND POLITICAL LIFE

VII AN INTELLECTUAL IN BUSINESS

VIII THE DESCENDANTS OF MICHEL SARRAZIN

IX SUCCESSORS OF SARRAZIN

It need scarcely be told that Dr Sarrazin was essentially a worker, and found little time for relaxation, unless his scientific avocations could be so described. In political matters he was always active, having been elected to the Conseil in 1707, and he was honoured by being appointed Keeper of the Seals in 1733. He did not marry until his fiftieth year, but made a fortunate union then with the young Marie-Anne Hazeur, a lady of good family and position, whose father had owned large properties in the region of Gaspé, and was also Seigneur of Malbaie (Murray Bay). He himself, though apparently of little or no means on his arrival in the country, had become at this time a large proprietor. The remuneration of a "Médecin du roi" was not high, but due to repeated representations on his behalf by the Governors of the colony and others of his friends high in office at Quebec, his salary, which began in 1699 at 300 livres, was raised in 1702 to 600, in 1703 to 800, in 1709 to 1,100 livres, and in 1717, when his petition for an annuity of 400 livres for his son to study medicine in France was granted, it rose to the very considerable sum of 2,000 livres per annum. Desirous of obtaining for his growing family a worthy patrimony, he invested in what should have become extremely valuable land, namely, the fief of St Jean, an area of six acres, comprising about a quarter of that occupied by the present city of Quebec, and running from the river St Charles to the Grande Allée, as well as the fiefs St François and Ste Genevieve (with manor house attached and many buildings), for the sum total of 7,400 francs by deed of sale dated October 22, 1709. He had

also a house on the rue St Louis and another on the rue Parloir. Through his wife he came into possession of other still more extensive properties in Gaspé, the fief de la Grande Vallée des Monts Notre Dame and the adjoining concession of l'Anse de l'Etang (from which he took the title by which he is known), and a part of the Seigneurie of Murray Bay. The possession of these combined seigneuries in his own right and that of his wife created him a Grand Seigneur, as is shown by the act of "*foye et hommage*" dated at Quebec July 10, 1726.

But misfortune overtook him in his last years. His house in the rue St Louis was burnt, depriving him of a rental of 600 livres a year, there was a fall in the paper money of the time, and, worst of all, the failure of slate quarries which had been discovered on his Gaspé property, and in the operation of which he had become heavily involved, reduced him and his family to actual poverty. He died of a malignant contagious fever brought from a ship and caught by him from patients in the Hôtel Dieu of Montreal, where he died after two days of illness on the 6th of September, 1734, in his seventy-fifth year. He was buried without ceremony or éclat in the cemetery of the poor. He was survived by his widow and five children. Of the latter, two only lived to have descendants, Claude Michel Sarrazin de l'Etang, who returned to France, and whose name died in his female succession of the next generation, and Charlotte Angelique, who married Jean Hippolyte Gauthier de Varennes and founded an important French family that survives through several branches in the Province of Quebec to day. His humble ending did not prevent the public from acclaiming on all sides his goodness and charity and knowledge. His best epitaph was inscribed by the Religieuses of the Hôtel Dieu of Quebec in their register at the time and reads:

"For more than forty-five years he exercised his art in this country with rare charity, perfect disinterestedness, extraordinary success, surprising address, and an unparalleled devotion for every kind of person, which rendered him able to perform with joy and grace all that lay in his power for the relief of the sick under his care."

The last chapter of this volume visions the future of French Canadian medicine under the title "Les Successeurs de Sarrazin." Space does not permit us to enter upon this topic nor have we been able to dwell adequately upon the interesting subject of Dr Sarrazin's social and political relations. But the book is there to be read and enough has been said here to show not only what manner of man this was whom we must acclaim as the pioneer of scientific medicine in this country, but also that Dr Vallée's exposition is a solid contribution to the history of medicine on this continent of which the Canadian profession must be most justly proud.

possibly get in their homes. The "King Edward's Fund," which controls much of the money allotted to hospitals, has recently published the findings of its committee on the provision of pay beds in the voluntary hospitals. It is estimated that about 7,000 beds are needed in London and about 1,000 are at present provided. Many hospitals are adding "private wards," but so often there is difficulty over charters and funds left for charitable purposes that separate endowment is often required. When the private patient is admitted there is at once the demand for the practitioner concerned with the case to be allowed to attend, and very frequently there is a lot of squabbling over fees, while it is rightly urged that until the full cost of a pay bed in a voluntary hospital has been met there should be no fee for attending consultants. It will be seen that the problem is not an easy one, and it cannot be said that the latest report offers a complete practical solution, although it has very satisfactorily ventilated most of the difficulties.

Medical men in London have recently had sent to them a small pamphlet entitled "A Garden of Rest" in which some account is given of the

well-known crematorium at Golders Green, and the very beautiful details there set out suggest that some move ought to be made to get rid of many of the disabilities which militate against cremation in this country at the present time. It is extremely difficult and very expensive for the poor to obtain cremation and the existing legal requirements are very stringent. It is reported that the Home Secretary is revising the statutory rules and orders made under the Cremation Act and this, combined with some support of cremation by the public health authorities, may lead to an extension of the practice to the poorer classes. Most of the old village churchyards are now full, and new cemeteries are being opened, at very heavy cost, all over the country. Better, it is suggested, that the money thus expended be used for establishing a crematorium in each community and let the urns be interred in the church yards. There were only just over 3,000 cremations in this country in 1927 as compared with over forty-five thousand in Germany in the same period, so that there is considerable room for extension here.

ALAN MONCRIEFF

Letters to the Editor

USE OF SULPHO-CYANATE OF SODIUM IN HIGH BLOOD PRESSURE

Dear Sir

Dr A G Smith and I gave a paper at the last meeting of the Canadian Medical Association on the "Use of Sulpho-Cyanate of Sodium in High Blood Pressure," which appeared in the September issue of your *Journal*. The subject seems to have aroused unusual interest and I have had many communications in regard to it from physicians in different parts of the country. This is satisfactory but unfortunately in several instances our suggestions regarding dosage have not been followed, with regrettable results, and this letter is in the form of a warning lest a drug which promises well should get a bad name from improper use.

Dr J B Nichols of Washington, whose paper in the *American Journal of the Medical Sciences* (November, 1925) aroused our interest in the agent, recommended a dose of 15 grains a day. In our research we commenced with this amount but soon found that it was better to use smaller ones, and in our paper we recommended $2\frac{1}{2}$ grains twice or three daily. Even with 15 grains daily we got no untoward results except occasional nausea, but the smaller dose reduced the blood pressure equally well (although more gradually), and hence in our later work we gave

only $7\frac{1}{2}$ or even 5 grs in the twenty-four hours and this is the dose that we recommended.

But certain doctors have far exceeded even Nichols' dosage and write to me asking if possibly the resulting symptoms could be due to the drug. "The answer has been in the affirmative" as they say in the Legislature. I give a couple of typical examples—

(1) A medical man from the east writes that having heard our paper at Charlottetown he treated a patient as follows: "I gave her a few doses of 5 grains each, and one dose of 15 grains after the evening meal. The doses were given after meals three times daily. The symptoms following the evening dose of 15 grs have been rather alarming,—vomiting all night, and next morning jaundiced. Twitchings of the muscles and attacks of rapid heart. Blood pressure 172/120 (It was 240/140 before). Next day it was 208/140, twitchings less pronounced and jaundice clearing up, but heart keeps pounding and rapid. Of course no further doses of the drug have been given. I would be glad to know if a further use of the drug would be advisable."

(2) A doctor telephoned over the long distance to say that he had a patient with a blood pressure of 240/140 to whom he had given a number of 10 gram doses of sodium sulphocyanate every three hours. She was now

drowsy and in a stupor and would like to know if this was due to the drug

Now most valuable medicinal agents which are harmless in medicinal doses are toxic in massive ones and sodium sulphocyanate is no exception

I hope that this letter may appear in an early number of the *Journal*, as we feel a certain indirect responsibility and fear that if this drug is misused it may do much harm

To repeat, the dose of sodium sulphocyanate, in our opinion, should be five to seven and a half grains in the twenty-four hours, and in this amount it is free from risk and often is valuable in reducing blood pressure, when such reduction is indicated

I am, Sir, Yours faithfully,

R D RUDOLF

Toronto, September 29, 1928

AN UNUSUAL TYPE OF SUPERNUMERARY DIGIT

Dear Sir

In looking through the September number of the *Canadian Medical Association Journal* I came across an article by Dr Corrigan of Lampman, Sask, describing "An Unusual Type of Supernumerary Digit," the said article displaying a photograph of a rudimentary sixth finger attached by a pedicle to the little finger of a baby's hand. I was struck by the photograph and would like to tell you about a case that came under my notice on Sunday, September 30th. On that date I confined a patient, a young French Canadian woman. It was her sixth pregnancy. When the baby was born, a girl weighing eight pounds, I was surprised to see attached to each little finger by a pedicle a tiny supernumerary digit, the exact counterpart of the photo given by Dr Corrigan in his article. To make matters more interesting, the mother told me that out of her six children five had had little extra fingers, very similar to the baby born on Sunday, September 30th. She told me that the only child without the extra fingers was the one I brought into the world about thirteen months ago. This morning I ligated the pedicle with a silk suture and snipped off the little digits. One ligature slipped and there was quite a little bleeding until I applied another.

I enquired whether any other members of the family, either on her side or on her husband's had ever shown this tendency to have more than the normal number of fingers. She told me that one of her brothers had a webbed toe, but no other member of the family ever showed this abnormality except her own children. I am prompted to write you for two reasons (1) because of my seeing to-night by chance Dr

Corrigan's photograph of his case, which is an exact picture of my own, and (2) because I thought it most unusual to find five children out of a family of six with extra digits

Yours truly,

A R BAYNE

La Tuque, Que., October 2, 1928

AUTOMOBILE ACCIDENTS AND THE HOSPITALS

Dear Sir

The increasing number of automobiles on the roads of this country has provided a series of problems many of which are still unsolved

To the medical profession the victims of automobile accidents provide a problem of great importance and this problem is shared by the hospitals. The hospital receives what is left of the human wreckage after a motor disaster, and the staff is expected to provide immediate skillful treatment for which they are infrequently paid. It is this expense item which is proving such a burden on our hospitals.

At the time of the accident it is impossible for the institution to refuse admission to the sufferer, and this fact is taken advantage of by the persons involved in the smash. Once the injured patient is dumped on the hospital the squabble as to responsibility begins. This controversy is frequently long drawn out and the settlement indefinitely postponed. In the meantime the hospital is unpaid. Again, it happens that a claims' agent will arrange a settlement by agreement, without including the hospital in such settlement. A great many of the pedestrians injured by motor cars are poor and unable to afford the litigation which is often so necessary to obtain compensation. Their poverty is also a barrier to successful collection of a hospital bill from themselves.

In recent years a large group of tourists travel long distances in cars of little or no value. When such a gypsy tourist is involved in a smash the victims are a charge on the nearest general hospital, and there is practically no chance of collecting hospital charges, for the tourist is a stranger, his car is cheap and damaged and is frequently deserted after a smash.

All of these circumstances make it apparent that an unnecessary burden is placed on the general hospitals, which burden is increasing with the increasing number of motor vehicles.

It is very likely that legally a motor vehicle could not be classified as a lethal weapon but where a pedestrian is the victim of an automobile assault one may presuppose that the pedestrian did not run into the motor. Thus in the larger number of cases the motorist should at once be held responsible for necessary hospital

bills of his victim. In the case of injury of any individual where two motor cars are involved it should be laid down that no settlement should be completed before receipted hospital bills are produced. The details of this problem would necessitate the provision of suitable legislation and the co-operation of hospitals, insurance companies, and motorists' associations.

At present the hospital expenses of automobile accident cases is largely a charge on the general hospital which is supported either by

charitable endowment or by public taxation, whereas it should be directly charged to the agent causing the injury.

There is an effort at present being made in Great Britain to provide legislation along this line and I feel that the problem is sufficiently acute to be of interest to your readers.

Yours truly,

A STANLEY KIRKLAND

Saint John, N B, October 13, 1928

Provincial Association Notes

ANNUAL MEETING OF THE ALBERTA MEDICAL ASSOCIATION

The annual meeting of the Alberta Medical Association was held in Edmonton on September 18, 19 and 20, 1928. One hundred and ninety-six registered.

At 9:30 a.m. the business meeting commenced, with Dr. W. A. Scanlon, President, in the chair. The minutes of the last meeting were taken as read.

The report of the Executive Committee was read, showing the post-graduate work that had taken place in the province during the last year. On motion this was approved of.

On motion, it was decided to continue to celebrate Lister Day in a suitable manner.

A letter was read from the General Secretary of the Canadian Medical Association, stating that at the last Canadian Medical Association convention it was decided that the fees would be due and payable on October 1st instead of January 1st each year. On motion this action was concurred in by the Alberta Medical Association.

A letter from the General Secretary, stating that the Canadian Medical Association approved of having field secretaries, and legislative committees for the provincial associations was read and referred to the Council of the College of Physicians and Surgeons to deal with as they saw fit. The meeting then adjourned.

The scientific program commenced after the above adjournment.

During the convention His Honour Lt.-Gov. Egbert, M.D., delightfully entertained the delegates and their wives at a garden party on the lawn at government house.

The adjourned business meeting was held on the evening of September 19th.

In the absence of Dr. Emerson Smith, Mr. W. G. Hunt acted as secretary.

The report of the Committee on the question of the establishing of a Canadian College of Physicians and Surgeons was presented by Dr. J. S. McEachern, as follows:

"The Committee, consisting of Drs. J. S. McEachern, Fred Campbell and L. C. Conn, appointed to report on the communication from Dr. F. N. G. Stair, re a Canadian College of Physicians and Surgeons, has met and considered the question.

"Your Committee is unanimous in the opinion that the Alberta Medical Association should endorse the movement to establish such a College and give it its full support."

On motion of Drs. J. S. McEachern and L. J. Clarke it was resolved that the Report of the Special Committee, re the establishing of a Canadian College of Physicians and Surgeons, be adopted.

In the absence of Dr. G. M. Reid, the Treasurer, the Associate Secretary presented the Treasurer's report. The receipts were \$402.44 and the expenditure \$319.68, leaving a balance of \$82.76. This was received and adopted, on the understanding that it be audited and filed.

The next question on the agenda was that of the continuation of the post-graduate clinics, and it was unanimously agreed that we ask the Canadian Medical Association to continue the post-graduate clinics along the lines of the past few years.

It was moved by Dr. G. E. Lealmonth, seconded by Dr. T. H. Whitelaw, and carried —

"That this annual meeting of the Alberta Medical Association desires to place on record its appreciation and gratitude to the Canadian Medical Association for the post-graduate courses which have been put on in Alberta the last three years, also for its great assistance rendered at the annual conventions. The men sent to us have been of high standing and have rendered invaluable services to the profession in this province for which we are profoundly grateful."

Some discussion arose over the interesting information gathered by Dr. Heber Jamieson concerning the Alberta Medical Association, and printed on the banquet menu card.

It was moved by Dr. Walter Park, and seconded by Dr. I. R. Bell, and carried.

"That this association purchase sufficient copies of the *memorandum* to send to all the members of the profession in Alberta, whose names do not appear on the register this year as attending the convention, and to all those who were present who apply for the same.

"Further the cost to be as stated, viz, 25 cents per copy."

The report of the nominating committee was presented by Dr Keillon as follows: *Hon. President*, Dr A Gillespie, Edmonton, *Past President*, Dr W A Scanlon, Edmonton, *President*, Dr P M Campbell, Leithbridge, *First Vice-President*, Dr R Parsons Red Deer, *Second Vice-President*, Dr T R Ross, Drumheller, *Secretary*, Dr H A Gibson, 216 6th Ave West Calgary, *Treasurer*, Dr J D Robinson, Banff, *Executive Committee for 1929-1930*: Dr R R Elder, Medicine Hat, Dr W T Hynes, Lacombe, Dr B R Mooney, Edmonton, Dr R R Hughes, Calgary.

Representatives on the Council of the Canadian Medical Association in addition to President and Secretary: Dr H H Hepburn, Edmonton, Dr L J O'Brien, Grand Prairie, Dr W A Lincoln, Calgary, Dr F A Nordbye, Camrose, Dr A G Scott, Bassano.

The report of the nominating committee he received and adopted.

The question was raised as to the appointment of representatives to the Council who later might be unable to attend, and after discussion it was moved by Dr W A Lincoln, seconded by Dr C W Huilbert, and resolved "That the President and Executive Committee ascertain who are able to attend the Council meetings of the Canadian Medical Association, and be herewith given power to appoint others to fill the vacancies caused by those who cannot be present."

On motion of Drs Lincoln and Ross, it was resolved "That we appoint the present Editorial Committee to be the Committee for 1929, as follows: Drs G E Learmonth, Chairman, H C Dixon, P M Campbell, Harold Orr, and T H Whitelaw."

The President, Dr Scanlon, raised the question of the expenses of the Secretary to the Council Meetings of the Canadian Medical Association, stating that, according to a former resolution, it was decided that this Association would pay the expenses of the President or his authorized appointee, and fifty dollars towards the expenses of any or all other official representatives to the Canadian Medical Association. The Association decided to make no change in their former action.

It was stated, however, that the Council of the College of Physicians and Surgeons was willing to pay the expenses of the Secretary to attend the Council of the Canadian Medical Association, therefore it was moved by Dr

Somerville, seconded by Dr Edgar Allen, and carried "That we thank the College of Physicians and Surgeons for their offer and accept it, and further that the whole question be referred to the incoming Executive with power to act and to bring in a recommendation for the consideration of the next annual meeting."

It was decided that the time and place of meeting of the next convention be left with the new Executive Committee.

Dr Routley was present part of the time and told the Association something of what was being contemplated in the matter of organization in the other provinces. The Maritime Provinces were considering the question of a full-time travelling secretary for their three provinces. Manitoba and Saskatchewan were also considering the question of a travelling secretary.

He stated that none of the other associations paid the expenses of their delegates to the Council of the Canadian Medical Association.

W G HUNT,

Acting Secretary

ANNUAL REPORT OF THE GENERAL SECRETARY OF THE PROVINCE OF QUEBEC MEDICAL ASSOCIATION FOR THE YEAR 1927-28

A summary of the activities of the Association for the past year indicates that they were varied and numerous. After the Clinical Day held in Montreal last year, the President, Dr Stevenson, held a meeting of the Executive Committee, to elaborate a plan of work and action for his term of office. Proud of the success of his predecessor, he continued in his steps and his first effort was to put in practice the advice that had been given to him.

At this first meeting of the Executive, a committee for the study of the Workmen's Compensation Act was established, and also committees on Illegal Practice, on the Recruiting of Members, and the formation of Medical Regional Societies. These three committees were well completed by the Post-Graduate Committee which had been functioning in a very efficient manner.

The Executive Committee took under its charges the recruiting of members and the formation of Medical Regional Societies, with the help of the Post-Graduate Committee. We now show an increase of more than 400 new members, which added to the 250 of last year, brings our membership up to a total of more than 650, which is more than 25 per cent of the medical profession that endorses the movement and the ideas of our Association.

By the articles published in the medical reviews of the Province of Quebec, and more par-

ticularly in the *Union Médicale du Canada*, in the *Bulletin Medical de Québec*, and in the *l'Action Médicale*, numerous demands for the formation of Medical Regional Societies were addressed to us. With the help of a certain number of doctors of the district of Montmagny, visited by the lecturers of the Post-Graduate Committee, the Société Médicale du comté de Montmagny was brought back to life, and with the help of the physicians of the counties of l'Islet and Bellechasse, the Société Médicale des comtés de Montmagny, Bellechasse et l'Islet was founded.

Dr F. L. Dubé solicited our help to organize a District Medical Society, la Société Médicale du District No. 1, comprising the counties of Témiscouata, Kamouraska, Rimouski, Matane, Matapédia, Bonaventure, Gaspé and les Îles de la Madeleine, all counties corresponding to the counties of the district No. 1, of the College of Physicians and Surgeons of the Province of Quebec. We got in touch with the president of l'Association Médicale des comtés de Témiscouata et de Madawaska and at the meeting of the doctors of that Society, at which were convened the doctors of District No. 1, the first District Medical Society was founded, amidst an enthusiasm which was most gratifying.

The doctors of the counties of Charlevoix and Saguenay, isolated one from the other, conceived the idea of reviving the local Medical Society, which had been more flourishing many years ago. Again with the help of the Post-Graduate Committee, which delegated lecturers in that region, the foundation of La Société Médicale des comtés de Charlevoix-Saguenay became a fact, and it promises to be one of the most active of the regional societies.

The Committee on the study of the Workmen's Compensation Act and the Committee on the Illegal Practice report progress. These two committees assisted and defended the interests of the profession at large before the Provincial Government, jointly with the representatives of our universities and of the College of Physicians and Surgeons, and also with the help of the medical members of the legislature, who worked hand-in-hand to have the interests of the profession passed before the interests of the parties and endeavoured to protect certain rights of the medical men in connection with the new Workmen's Compensation Act. One result was that the government finally rejected the demand for establishing a school of chiropractics in Montreal.

The Post-Graduate Committee, which has already an existence of three years, is certainly the one which has the biggest amount of work.

To date, twenty-two clinical meetings were held throughout the province, and more than six hundred doctors were present at the meetings. These lectures are still functioning, but, the fiscal year of the committee terminating on September the 30th, it is impossible for us to present a complete report of these meetings.

The Association had its representatives at the annual meeting of the Canadian Medical Association at Charlottetown, and Drs. Stevenson, Bazin and Lynch defended the interests of our profession, in the Council of the Association. Among other matters, it was decided at that meeting, that to become a member of the Canadian Medical Association, it was sufficient for a doctor to be in good standing with his College of Physicians and Surgeons and to be a member of a Provincial or a National Association. For instance, a doctor in good standing with l'Association des Médecins de Langue Française de l'Amérique du Nord, and who for one reason or another does not belong to the Province of Quebec Medical Association, could apply to become a member of the Canadian Medical Association and such a qualification would be sufficient.

It was decided that the year of the Association would start January 1st. Consequently, the existing Executive Committee will continue to act until that date, and the new Executive Committee which will be elected very shortly will direct the Association from that date.

The next annual meeting will be held in June in Montreal, when the Canadian Medical Association will be our host.

Finally, the Executive Committee held five meetings, in which most of the members took part. Besides the ordinary questions which were presented, the agenda contained numerous articles for the preparation of the Annual Clinical Day in which we obtained a very great success. We cannot but laud the great effort which the local committee on arrangements excited in preparation for this annual meeting and particularly the work of the local Secretary Dr. Cabana who devoted his time and energy to bring this meeting to a complete success, of which not only the doctors of the City of Sherbrooke, but the entire population might be proud. In terminating this report, may I be allowed to thank, in the name of all the members of the Province of Quebec Medical Association, the local committee on arrangements, and especially the Secretary, who is always the working head, to all of whom the success of this annual Clinical Day is most entirely due.

LÉON GÉRIN LAJOIE

Medical Societies

XI^{me} CONGRÈS DE L'ASSOCIATION DES MÉDECINS DE LANGUE FRANÇAISE DE L'AMÉRIQUE DU NORD

This Congress was held in the City of Quebec from September 5th to 8th. An important delegation from France was present, consisting of Professor and Mme C. Jeannin, Professor and Melle Lereboullet, Dr and Mme P. Desfosses and Drs Simon, Charpentier and Leclerc.

The opening meeting, on Wednesday September 5th, was presided over by Dr P. C. Dagneau, Professor of Anatomy in Laval University and he was supported on the platform by the Hon. Athanase David, Provincial Secretary of Quebec, Mr Oscar Anger, Mayor of Quebec, Mgr Gosselin, Rector of Laval University, Dr Arthur Rousseau, Dean of the Faculty of Medicine, and the French delegates. Some 425 physicians of the French tongue attended from various parts of Canada and the United States. Several felicitous addresses of welcome were delivered.

In the afternoon Prof. Jeannin of Paris gave an address on "The treatment of puerperal infections after the method followed at the Obstetrical Clinic of the Pitié at Paris." His statements were based entirely on personal experience. At the Pitié, in 12,500 confinements there were 328 infected cases, a proportion of 2.3 per hundred. When one notes that the total mortality during the post-partum period is from 0.55 to 0.60 per cent and that puerperal infection alone accounts for one-quarter of these, the importance of the subject may be realized. The total mortality in puerperal septicæmia ranges from 12 to 66 per cent.

Professor Jeannin laid special emphasis on the plurality of puerperal infections. The conception of the condition as of single derivation has been productive of the worst therapeutical errors. On the contrary, for each form a specialized treatment is necessary.

He laid down the principal lines of treatment as follows:

In low grade infections local treatment in the form particularly of applications of lactic pap, (pansements à la bouillie lactique).

In case the uterus retains products of conception, it should be cleaned out. If it does not, reliance should be placed upon local tissue infiltrations, such as Besredka's method. The uterus should not be interfered with.

Infection of the broad ligaments calls for surgical intervention only if suppuration occurs.

When peritonitis supervenes laparotomy should be performed as quickly as possible. Professor Jeannin obtained four cures in seventeen cases operated upon.

When suppurative phlebitis occurs the focus may be isolated by ligature, or removed by

excision. However, interference should not be too hasty. The best results are obtained usually at about ten days after delivery.

In conclusion, the speaker stated that we were still comparatively helpless in handling these cases. The value of arsenobenzol and serotherapy was still to be established.

Professor Caouette, of Quebec, followed with a very full and well reasoned paper on "The usual causes and the prophylaxis of puerperal infections." In 237,199 births that took place in Canada from July 1st, 1925 to July 15th, 1926, there were 1,532 maternal deaths, or 6.4 per 1,000. Of these 1,532 deaths puerperal sepsis was the cause in 33 per cent. The best way to combat puerperal sepsis was for the obstetrician to maintain the same careful aseptic technique that was incumbent on the surgeon.

Dr Dubé, of Notre Dame du Lac, discussed the subject as it appeared to the country practitioner.

Dr L. Gérin-Lajoie, of Montreal, described the practice of the gynecological clinic of the Notre Dame Hospital in regard to puerperal infection, as follows: (1) Light diet, (milk and vegetables), (2) Local treatment, as ice to abdomen, very hot vaginal douches, warm rectal irrigations, (3) General supporting treatment, as camphorated oil, brandy, good nourishment, (4) General treatment directed against infection, such as the use of propidon alternating with electrargol or septicemine. The total mortality of their cases, including many of the greatest severity, had not exceeded 25 per cent.

Professor Fortier, of Quebec, read a very carefully prepared study of puerperal endocarditis, and was followed by Dr Vaillancourt on the "Ocular complications of puerperal infection."

The discussion on puerperal sepsis was continued the following day. Dr Louis Phaneuf, of the Carney Hospital, Boston, stated that the American School advocated conservative, rather than radical, procedures. The vaginal examination was discontinued entirely in Boston.

Dr Georges Labey, of Paris, discussed "Abscess of the uterus of puerperal origin." There were two forms, military abscesses and larger collections of pus occupying the whole thickness of the uterine muscle. Diagnosis is difficult in these cases. The principal symptom is pain in the uterus. The discovery of a swelling on the surface of the uterus is suggestive. Surgical intervention at once is indicated. Without it the prognosis is hopeless. He rejected the vaginal route. Well localized abscesses may be drained, but in most cases a total hysterectomy with Mikulicz drainage is required.

Dr F. de Martigny spoke in favour of vaginal hysterectomy. He thought it was the most radical operation and produced the least shock.

In about 5 per cent of cases of puerperal infection it was necessary to interfere surgically

Dr Oscar Mercier described the pyclo-nephritides which sometimes, though rarely, followed delivery. It was not enough in cases of developing infection to examine the uterus, but the urine should be examined as well. Treatment at first should be medical. Only after this failed was ureteral catheterization indicated, to drain the kidneys.

Professors Brousseau, Caion, and Laue spoke on the mental syndromes associated with puerperal infection.

The following day was given up to the discussion of the important question of diphtheria.

Professor Lercboullet, of Paris, dealt very fully with the question of treatment and prophylaxis. During the attack anti-diphtheritic serotherapy should be instituted early and be intensive and prolonged. He referred to the ordinary antitoxic serum of Roux and the purified form put out by the Pasteur Institute, the latter was not followed by dangerous accidents. The purified serum was to be preferred in the ordinary and larval forms of angina, in asthmatics, in those who had previously been injected, and, generally, in adults. The ordinary serum (Roux) was, generally speaking, to be preferred in malignant diphtheria. It should be employed in massive doses, a minimum of 200 c.c. a day, repeated for four or five days. It should, of course, be discontinued if anaphylactic reactions occurred. He thought that local treatment in diphtheria was useless. As adjuncts to the treatment he advised adrenalin, strychnin, camphorated oil, and sometimes ouabain. Anti-spasmodics were also sometimes of value and warm compresses about the neck. He pointed out that immunization did not always follow an attack of diphtheria, and he thought it good practice to follow up the case, on convalescence, with three injections of anatoxin-Ramon at intervals of two or three weeks.

Dr Lapierre, the Director of the School of Social Hygiene of Montreal, discoursed on the benefits of antidiphtheritic vaccination. Anatoxin-Ramon established an immunization in from six to eight weeks and was absolutely harmless. He thought the procedure should be carried out at the end of the first year of life.

Professor L. N. Fiset gave a complete review of the question of diphtheritic paralysis. According to certain American statistics it occurred in from 10 to 11 per cent.

The last day was given up to the discussion of various problems in psychiatry.

Besides the formal papers and discussions, clinical demonstrations were given in the various hospitals of Quebec.

It was passed unanimously by the Congress (1) That only those children should be admitted to school who came provided with a certificate of anti-diphtheria vaccination.

(2) That anti-diphtheritic serum and vaccine

should be supplied to poor families by the municipal organizations.

The election of officers resulted as follows: President, Dr P. L. Rhéaume, of Montreal; Vice-Presidents, Drs Albert Paquet, of Quebec, L. E. Phaneuf, of Boston, and Dr P. H. Laporte, of Edmundston; Secretary, Dr D. Marion, of Montreal.

The next Congress will be held in Montreal in 1930.

ONTARIO MEDICAL ASSOCIATION

ANNUAL MEETING OF DISTRICT NUMBER TWO

District number two of the Ontario Medical Association met in annual session at the Norfolk Golf and Country Club, Simcoe, on Tuesday, September 25th, with an attendance of about seventy-five members.

At two o'clock in the afternoon the meeting was opened with a short business session at which Dr A. J. McGarity, of Kitchener, was re-nominated Counsellor for the District, and Drs W. A. McIntosh, of Simcoe, and F. J. Burrows, of Seaforth, were elected Vice-counsellors for the ensuing year.

A communication was received from the Oxford County Medical Society extending a very cordial invitation to the members of the District to hold the next annual meeting in that county.

Dr Robert T. Noble, official representative of the College of Physicians and Surgeons of Ontario, then gave a review of the medical and narcotic drug acts, dealing with some difficulties which have arisen out of their attempted enforcement.

This was followed by a paper on "The thyroid subject" by Dr J. K. McGregor of Hamilton, and a brief address by Dr T. C. Routley, Secretary of the Ontario Medical Association, dealing with many matters of importance to members of the medical profession at the present time.

At four o'clock, the meeting adjourned in order that those present might have an opportunity of visiting the Norfolk Historical Museum and the grounds of Mr H. J. Brook.

Dinner was served at 6.45 o'clock at the Norfolk Golf and Country Club, followed by short addresses by Dr Weston Krupp of Woodstock, immediate past President of the Ontario Medical Association, and Dr Waid Woolner, second Vice-president. The concluding address of the evening was given by Dr Thos B. Fletcher, of Baltimore, on "Lesions of the pituitary gland and hypothalamic region, in relation to the etiology of diabetes insipidus."

A very enjoyable day was spent by all who availed themselves of the opportunity of attending this meeting. The cordial hospitality of the local committee and their wives left nothing to be desired, and the meeting was in every way a decided success.

ANNUAL MEETING OF DISTRICT NUMBER NINE

The annual meeting of the southern section of district number nine of the Ontario Medical Association was held in Sudbury on Thursday, September 6th, with an attendance of more than sixty. Dr W J Cook, of Sudbury, presided and was renominated for the position of Counsellor, while Dr A S McCaig of Sault Ste Marie was elected Vice counsellor for the southern section of the district.

At 9 30 a m, Dr F F Tisdall, of Toronto, gave a talk on "Deficiency diseases," followed by Dr A Primrose in an address on "Intestinal obstruction."

At 11 30 a m, the meeting adjourned to the Grand Opera House where Dr Cauti's film on "Growth of tumour cells *in vitro*, and the effect of radium thereon" was shown, accompanied by an explanatory address by Dr James Miller, Professor of Pathology, Queen's University, Kingston.

Luncheon was served at the Nickel Range Hotel, after which Dr Roscoe Graham, of Toronto, gave an address on "Gottie." This was followed by a talk by Dr Ross Millar, Ottawa, Director Medical Services, D S C R, on medical problems relating to soldier's civil re-establishment.

Dr Robert T Noble of Toronto, who was present as the official representative of the College of Physicians and Surgeons of Ontario, then gave a brief review of the medical and narcotic drug acts, calling attention to some of the difficulties arising out of their attempted enforcement.

The dinner in the evening was followed by brief addresses by Dr E A McQuade, Trenton, President of the Ontario Medical Association, Dr A Primrose, Chairman of Council of the Canadian Medical Association, and Dr T C Routley, Secretary of the Ontario Medical Association. Dr J C Meakins, of Montreal, then gave the final address of the evening, his subject being "Arterial hypertension, its significance and treatment."

One of the matters which was brought up for discussion at the brief business session was the care of drug-addicts, and a resolution was passed with the unanimous approval of the meeting memorializing the provincial government to provide adequate hospital accommodation for drug-addicts, and also to make provision for their committal thereto.

Following the afternoon program, the members and visitors enjoyed a round of golf. With excellent weather and unsurpassed hospitality on the part of the local committee and their wives, the meeting was one of the finest ever held in the district.

ANNUAL MEETING OF DISTRICT NUMBER TEN

The annual meeting of district number ten of the Ontario Medical Association was held in Fort William and Port Arthur on Saturday, September 8th, with an attendance of about forty.

The morning session, which was held at McKellar General Hospital, Fort William, was opened with an address by Dr J C Meakins, of Montreal, on "Arterial hypertension, its significance and treatment." This was followed by a paper on "Common errors in the diagnosis of children's diseases," by Dr F F Tisdall, Toronto.

At eleven o'clock, adjournment was made to the Royal Theatre, where Dr Cauti's film on "Growth of cells *in vitro*, and the effect of radium thereon" was shown, with an explanatory talk by Dr James Miller, Professor of Pathology, Queen's University, Kingston.

After luncheon at the Kamistikwia Club, Dr Roscoe Graham, of Toronto, gave an address on "Gottie", followed by a talk on "Intestinal obstruction" by Dr A Primrose.

Dr Ross Millar, of the Department of Soldiers' Civil Re-establishment, Ottawa, then gave a brief talk on the work of his department calling attention to a few of the medical problems with which they have to deal.

Dr Robert T Noble, official representative of the College of Physicians and Surgeons of Ontario, was present and reviewed the medical and narcotic drug acts, pointing out some of the difficulties which have arisen out of their attempted enforcement.

It was the unanimous opinion of those present that addresses such as those given by Dr Millar and Dr Noble were of distinct value to the members of the profession, not only as a means of gaining first-hand information, but of clearing up any misunderstanding which may exist.

In the evening, dinner was served at the Prince Arthur Hotel, Port Arthur, following which brief addresses were given by Dr E A McQuade, President of the Ontario Medical Association, Dr A Primrose, Chairman of Council of the Canadian Medical Association, and Dr T C Routley, Secretary of the Ontario Medical Association.

At the short business session which was held, Dr J C Gillie, of Fort William, was renominated Counsellor for the district, and Dr Chas Powell of Port Arthur was elected Vice-counsellor.

The problem of the drug-addict was brought up for discussion and a resolution was unanimously agreed to, memorializing the provincial government to provide adequate hospital accommodation for drug-addicts, and also to make provision for their committal thereto.

While many very excellent annual meetings have been held in the district at the head of the lakes, it was the general feeling of the members that this one left nothing to be desired, either from the scientific or social point of view.

Topics of Current Interest

STANDARDIZATION OF THERAPEUTICAL PREPARATIONS

"The League of Nations has just published the report* of this year's meeting of the permanent Commission on the standardization of serums, serological reactions, and biological products. The problems dealt with by the Commission are highly technical, for the bio-assay of drugs involves methods in which every detail has to be regulated exactly if reliable results are to be obtained.

The work of the Commission is, however, of great service to the medical profession. In the first place it secures international agreement regarding the units of measurement to be used. This alone is a great advance, for medical literature is international, and the use in works of reference of units which differ in value in different countries may lead to dangerous confusion. In the second place it is most important to have really trustworthy methods for measuring the activity of biological products, and the Commission is doing valuable work by its careful and critical examination of the numerous methods of standardization that have been evolved.

The following is a summary of the more important conclusions arrived at by the Commission.

I—STANDARDIZATION OF ANTIGENS AND ANTIBODIES

(1) *Anti-diphtheritic Serum*

'In view of new facts brought to light by the phenomenon of flocculation occurring in the mixture of specific toxin and anti-diphtheritic serum the Commission decided to study the evaluation of anti-diphtheritic serum and of diphtheritic antigen (toxin and derivatives) by the flocculation method.'

(3) *Anti-tetanus Serum*

The Commission now proposes to adopt the following anti-tetanic unit:

'The unit is to be determined with a standard serum in such a way that its relation to the American unit is exactly 2 International to 1 American unit.'

(4) *Anti-dysentery Serum (Shiga)*

The Commission proposes 'to adopt a standard serum prepared and distributed by the Danish State Serum Institute to establish the international antitoxic unit.'

'The serum is prepared for distribution in such a way that 1 unit is contained in 1/200 of 1 c cm, and that a dilution in the proportion of 1:200 contains 1 unit in 1 c cm.

A test dose of a dysentery toxin shall be defined as such a quantity that, when 1 c cm of this serum dilution is mixed with it, the mixture shall cause death in one-third of the mice receiving it by intravenous injection.

When a toxin is standardized in this way it may be used in titrating the serums.'

(8) *Blood Groups*

The Commission

'I Learn with satisfaction that, on the initiative of the Health Organization of the League of Nations, the nomenclature proposed by von Dungein and Hirsfeld for the classification of blood groups has been generally adopted, and recommends that this nomenclature shall be adopted for international use, as follows:

O A B AB

To facilitate the change from the nomenclature hitherto employed the following is suggested:

Jansky	O(I)	A(II)	B(III)	AB(IV)
Moss	O(IV)	A(II)	B(III)	AB(I)

'II Recommends the adoption of the following method of designating test-serums:

Test serum A (anti B)
Test serum B (anti A)'

II—STANDARDIZATION OF THERAPEUTIC SUBSTANCES BY BIOLOGICAL METHODS

(1) *Salvarsan*

The Commission endorsed the recommendations at the Geneva Conference of 1925 with certain modifications. The chief alterations were that it was decided to recognize a test for experimental action on animals infected with spirochaetes as an alternative to that in which trypanosomes are used.

The Commission recommends that a 20 per cent excess of toxicity above that of the standard would be a suitable limit for tolerance. It also recommends 'that the standard samples for neosalvarsan and sulpharsphenamine provided by Professors Kolle and Voegtlin respectively for trial are suitable, as regards toxicity and experimental therapeutic activity, for adoption as the basis for the international standards.'

(2) *Digitalis*

No. 3. The Commission considered that they had now sufficient evidence before them to justify a somewhat wider recommendation with regard to comparative methods of testing than that adopted by the Geneva Conference of 1925. It considered that the following methods might be recommended as suitable:

'(a) The frog method in the form recommended by the Geneva Conference, or in its other modifications.

* Publications of the League of Nations III, Health, 1928, III, 6.

(b) The method using intravenous infusion in the mammal, as described by Hatscher and modified by Magnus and his colleagues for the cat, by Knaff-Lenz for the guinea-pig, or by Tiffeneau for the dog

(c) The Commission considered that the methods described by Mansfeld, using portions of the isolated sinus venosus of the frog, and by Trevan, using the isolated auricle of the rabbit, merited further investigation, with a view to consideration on a future occasion

The Commission also recommended

'That, when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed for any preparation and in any country should be an international unit, which should be defined as the specific activity contained in 0.1 gram of the international standard powder'

(4) *Insulin*

The Commission found that the results obtained by the use of the standard preparations recommended in 1925 'were uniformly favourable, and that the unit adopted and recommended by the Geneva Conference of 1925 was now in use all over the world as the only unit of insulin. In view of this satisfactory position the Commission decided to adopt the recommendations of the Geneva Conference of 1925 as regards the standard of insulin without modification

'That the dry preparation of insulin hydrochloride, prepared by the Medical Research Council of Great Britain, at the request of the Edinburgh Conference, should be accepted as the international standard preparation of insulin. That 1 milligram of this standard contains 8 units of insulin (or 1 unit = 0.125 milligram), as provisionally defined by the Insulin Committee of the University of Toronto'

(5) *Pituitary Extract*

'The Commission accordingly recommends, in the light of the uniformly favourable experience obtained since the Geneva Conference of 1925, that the dry preparation of the acetone-extracted fresh posterior lobe substance of ox pituitary be now definitely adopted as the international standard preparation for the biological evaluation of preparations of the posterior lobe of the pituitary body, whether containing all the active principles of the lobe, or the pressor or oxytocic principle only, in separate solution'

None of these conclusions requires much comment. In general it may be said that three years' experience in the use of the methods of standardization recommended at Geneva has shown that these are sound, and require only minor modifications

It is interesting to note that as regards biological standardization experience has confirmed the finding of the Geneva Conference that the only sound method of standardization is to compare the activity of the preparation to be tested with

a standard preparation of the same substance. For example, preparations of digitalis and the pituitary gland have to be standardized against standard preparations of these drugs, and experience has shown that it is not safe to attempt to standardize them against simpler chemical substances of known composition. For example, the methods by which digitalis was standardized against ouabain, and pituitary extract against histamine, are now recognized as unsound"—(*Brit. M. J.*, 1928, n, 3)

IRRADIATION AND THE BLOOD

"The enthusiasms that have been aroused by the demonstrable physiological potency of irradiation with ultraviolet rays generated in various ways call for restraint before they are permitted to promote therapeutic procedures that may presently be discovered to be ill advised. It is better that disappointments should precede rather than follow their use. Irradiation cannot be rationally employed until its possible effects on the organism are thoroughly investigated in many directions. The antirachitic effects of exposure to ultraviolet rays are so striking and easy of demonstration that there has been a tendency to expect only beneficial results from irradiation, regardless of intensity and 'dosage'.

Some of the effects on the blood and circulation have already been determined with sufficient accuracy to justify the proposed precautions. Not long ago it was shown by Miles and Laurens¹ that the exposure of dogs to carbon arc radiation may give rise to variable results with respect to the changes in the content of erythrocytes in the blood. Depending on the dosage, increases and decreases were noted. Their results were interpreted, however, to indicate a stimulation of the hæmatopoietic system. A continuation of the study, by Maverson and Laurens,² shows that changes in the plasma volume also may take place. For example, the primary result of an individual exposure was a temporary increase in the plasma with recovery to normal within a few hours. This dilution of the blood occurred again but was not augmented by further exposures, its duration being determined by the strength of dosage and the interval between successive exposures. After massive exposures a slight concentration followed the initial dilution. Repeated exposures stimulated the hæmatopoietic organs to produce an increased number of red cells that persisted for several weeks after the last irradiation. However, indexes of colour, volume and saturation showed that the red cells in the period after irradiation are usually smaller and less saturated than before the treatment. Furthermore, a progressive leukopenia may develop.

These are phenomena that must be evaluated

with some caution Mayerson and Laurens assert that erythrocytes may actually be destroyed by excessive irradiation with massive exposures. Such destruction is surely not a therapeutic desideratum. These investigators, who have had large experience in this field, believe that many of the conflicting results reported are without question due to the variation in the intensity and character of the radiation, the specifications of which are rarely given. However, as radiation does act as a hæmatopoietic stimulus to the normal relatively stable organism Mayerson and Laurens regard it as plausible at least that it would be particularly efficient in effecting regeneration in anæmic conditions. The persisting uncertainty should act as a warning against undue ventures that may actually border on quackery, until further explicit knowledge is available."—*J Am M Ass*, 1928, xc1, 1038

HOW CAN WE BEST PREVENT THE CONTRACTING OF COLDS?

"Here we would like to draw attention to the great danger just before our furnaces are lighted in the fall and after they are allowed to go out in the spring. At such times we are likely to sit in a temperature that is colder than the heat generated by our bodies can counteract. A temperature that is perfectly safe and even wholesome to move around in when we have a reasonable degree of physical exercise may be, and in fact is, a source of danger if we are sitting still or lying down. This should be our guide as regards additional clothing and heat.

Another not infrequent way by which the resistance of our bodies is reduced and the temperature lowered out of proportion to the amount of heat produced, is by getting wet or by cold and damp feet. In this case, there is necessarily an increased amount of evaporation going on and this is always attended by a decided loss of heat from the body.

On the other hand, there is the danger of dressing too warmly. This error applies more particularly to the so-called winter under-clothing which, as a matter of fact, should be very little, if any, heavier than that worn in the summer. We must bear in mind that in our homes, in our offices or places of business the temperature by our artificial means of heating during the winter time is practically the same as that which we enjoy in the summer time. Why, then, should we require any heavier clothing? The time for the heavier clothing is when we go outdoors into the cold air. If we

have heavy underwear, the chances are our skins will be bathed in perspiration, which will very materially expose us to cold when we go out, on account of the rapid evaporation of this perspiration.

Then there is the regulation of the diet. It must be borne in mind that our food constitutes the fuel and if it is not carefully selected it will not generate the necessary amount of heat, particularly in the winter. We require to see to it that our food is of such a character as will supply an ample number of calories. We must, therefore, choose food with heat-producing qualities—carbohydrates and fats.

In fact, the violation of any of the laws of personal hygiene has a tendency at all times to materially lower the resistance of our bodies and thus predispose us to colds or other diseases. Overwork, either physical or mental, so as to cause fatigue, also loss of rest and worry, all have a tendency to lower the vitality and constitute predisposing causes that are to be guarded against as far as possible.

Skin gymnastics are oftentimes beneficial. That is, it is well to begin in the early fall by taking tepid or cold baths or shower baths, or, if this is not convenient, to sponge the face, neck and chest with cold water every morning and to take occasional air-baths, that is, after the regular tub bath, whether it be warm, tepid or cold, and follow by a brisk rubbing.

All these have a tendency to give tone and resisting power to the surface of our bodies.

However, these are only auxiliaries. The main thing is to not leave anything undone that is essential to keep us physically fit. It must be apparent that proper nutrition, a properly balanced diet and the securing of a proper assimilation of our food and regularity of the evacuation from the body, both from the bowels and kidneys, are all extremely important."—*Health Bulletin*, Dept of Public Health, Toronto, Sept 22, 1928, vol 11

THE UNDERWEIGHT CHILD

"Undernourishment is a particularly menacing feature in relation to childhood because of the large numbers of individuals that seem to be involved, especially in certain parts of the world. As with any other deviation from the normal it is disconcerting, but notably so if it occurs at a period when maintenance of weight is not an index of welfare as it may be during adult age. Gain and growth are striking characteristics of the young. Undernourishment may be secondary to a variety of pathological conditions which make an otherwise adequate dietary ineffective. However, this is by no means the universal situation in the cases that commonly obtrude themselves on our notice. A recent study of underweight children by Wang, Hawks and

Hays* at the Nelson Morris Institute for Medical Research in Chicago indicates that the ability of such young persons to absorb and store nitrogen is fully equal to or greater than that of the usual "normal" child. Undernutrition therefore does not necessarily impair the alimentary functions, for the average absorption commonly exceeds 90 per cent of the intake. The fact that the nitrogen retention increases with the degree of underweight, as the experiments clearly show, indicates to the Chicago investigators that as the child gains in weight he is building muscular tissue as well as storing fat. Evidently the protein requirement of underweight children may be greater than that of the "normal" individual of the same age. Therefore, Wang and her co-workers conclude, in computing diets for underweight children, the protein as well as the caloric intake should be computed according to the standard, rather than the actual, weight of the child in question"—*J Amer M Ass*, Sept 15 1928

THE HISTORY OF HOSPITALS

"Some time ago it was not unusual to find in histories of the rise of Christianity on the ruins of paganism the statement that public charity to the sick and the establishment of hospitals were unknown before the days of Constantine the Great. A wider view of the ancient world, based on a greater knowledge of ancient society in Asia, as well as Europe and Northern Africa, has shown that hospitals for the sick were established long before the Christian era.

The Vicary Lecture on this subject, delivered by Dr George Parker of Bristol, has recently been published in the *British Journal of Surgery* (1928, xvi). Dr Parker has surveyed the whole field, and as a result of his studies is able to assure us that 'the earliest beginnings we know of can be traced to about the sixth century, B C, in places far apart, both in the West and distant East'. It is a curious and unexplained fact that there is no evidence of the existence of hospitals in Assyria, Babylon, early Egypt, or China. In the case of Egypt their absence is hardly surprising, seeing that the true Egyptian culture had disappeared by the sixth century, B C. It is, however, surprising that China, which so readily accepted Buddhist teaching, should not have adopted the Buddhist practice of founding hospitals, yet, as far as we know, there were no hospitals in China until, in quite recent years, they were established by Christian missionaries. We confess to some surprise at Dr Parker's statement that 'In England, besides monastic infirmaries, 577 hospitals and asylums were founded between 1100 and 1400'. As the population in 1400 is not likely to have exceeded three millions, and after the ravages of the Black Death was probably much less, this would give a ratio of

one hospital or asylum to every 5,200 of population, leaving out of account the monastic infirmaries which Dr Parker excludes. No doubt many, if not most, of these establishments were not hospitals in the modern sense of the word, but refuges for the sick poor, just as the existing St Bartholomew's Hospital was in its earlier days. This is a distinction which Dr Parker is careful to draw, but making as he does, large deductions on this account, the number of places for the treatment of the sick and wounded, in non-Christian as well as in Christian lands, is simply astounding. It is to Gautama and his followers that we owe, apparently, the hospital idea. Buddhist hospitals in India existed before the invasion of Alexander, which, moreover, only touched the northern part of that country. The Persians early founded hospitals and at Gondishapur we are told that there was a flourishing medical school, composed partly of Zoroastrians and partly of Nestorian Christians. In Greece, as is now well known, there were numerous institutions of the Aesculapian cult, where cures were wrought more by magic than by medicine. The more scientific Hippocratic schools do not appear to have had hospitals at their disposal, although there is not much evidence on this point. We cannot follow Dr Parker in his fascinating study of the Christian hospitals, and must content ourselves with a warm recommendation of his lecture to all who care for this interesting section of the history of medicine, nor will space allow us to do more than mention his researches into the history of Moslem hospitals, which are full of instruction for most of us"—*Brit M J*, 1928, ii, 540

CHRISTIAN SCIENCE AND THE DOCTOR

"Medical men who read the daily newspapers are probably aware that a schism has arisen in Christian Science ranks. The Christian Science Parent Church, some four years old, is considerably younger than the other member of the family, the Church of Christ Scientist. The word 'parent' is a little confusing, therefore, but it will be recalled that W S Gilbert raised much the same question in the case of the immortal Iolanthe, and some years ago (unless our memory has played us false) there used to be a standing debate on whether the hen was the mother of the egg or the egg the mother of the hen. It is not for us to comment on the heresy hunt which has started, but there is some interest in one of the points at issue—namely, the relationship of Christian Science teaching and practice to the medical profession. From literature sent to us by Mr John V Dittmore, contributing editor of the *Christian Science Watchman*, it appears that the Parent Church, founded by Mrs Annie C Bill in 1924, is convinced that the time has arrived for some recognition of the doctor by the Christian Scientist, or of the physician by the metaphysician, as Mrs Bill prefers to call him. Both Churches profess allegiance to the doctrines

* Wang, Chi Che, Hawks, Jean E, and Hays, Bertha B, Metabolism of Undernourished Children, V Protein Metabolism, *Am J Dis Child*, 1928, xxxv, 968

of Mary Baker Eddy, but the Parent Church produces ingenious arguments to show that the foundress of the faith was preparing the way for the recognition by her disciples of medical aid as an adjuvant of faith, when death ended the suffering for which she had been compelled to resort to injections of morphine. In the early stages of evangelization—so the argument runs—it was necessary to forswear medical methods in treating disease in order to emphasize the importance of 'methods of mind.' But the distressing fact remained that the majority of mankind rested its hope of recovery upon 'materia medica,' and since one of Mrs Eddy's axioms was that 'the greater controls the lesser,' it became easy to see that her sufferings were 'caused mainly by the majority of false beliefs of mankind.' Vain was the dismay of Mrs Eddy's students, vain then attempt to hide the doctor's visits, or prevent their leader's resort to the drug. While the majority of people continued to hold wrong beliefs Mrs Eddy could not escape from suffering. The time was ripe, therefore, for the second period of the crusade, the 'destruction of the degenerate element of wrong beliefs in which all disease originates.' And so Mrs Eddy took to morphine. The Parent Church alleges, with some show of reason, that the other group is illogical in its attitude towards drugs. Since all is mind, and there is no matter, it is plain that drugs are only a part of mind, or 'parts of the phenomena of the human mind.' Mrs Eddy was justified, therefore, in the intelligent utilization of the 'vehicle' of the human mind operating in that special mode. But the older type of Christian Scientist—the argument proceeds—is not justified in building hospitals, in miscalling them 'benevolent sanatoriums,' in preparing for the reception of diseased conditions, while all the time students of the cult are being taught that 'to permit disease to be present in the thought must bring it into the experience of the individual.' Far better that he should come over to the Parent Church, and invite the aid of the doctor in destroying the degenerate element of wrong belief by means of the immaterial vehicle, *materia medica*. It remains to be seen how far the physician will advance to meet the proffered embraces of the metaphysician, and co-operate in 'healing disease on the highest moral and spiritual basis,' so that 'Christian Science will be universally acknowledged to have brought to humanity the missing healing element of pure mental energy.' There is a type of mind within our profession which can discover in Hahnemann the father of rational dosage, and in Gall the

father of brain localization, for such it may not be too great an effort to regard Mrs Eddy as the mother of psychotherapeutics. In the meanwhile it is not without significance that there are Christian Scientists to-day who can allow to the medical practitioner some merit in dealing with disease, and it will be interesting to watch the effect of the new by-law of the Parent Church, which renounces commercialism and 'financial rivalry with medical specialists.'—*Brit Med J*, 1928, ii, 503

ON THE INTERPRETATION OF DECREASING MORTALITY RATES

"During the past twenty-five years mortality rates generally throughout the United States have had a downward trend. Different agencies undoubtedly have assisted in bringing about this fortunate situation. A preliminary report on five years of work in the health demonstrations of the Millbank Memorial Fund disclosed a reduction during the five years of approximately one-third in the death rate from tuberculosis and of nearly one-fifth in the infant mortality, which was attributed entirely to the health demonstrations of this memorial fund. It was also stated that the death rate in Syracuse from tuberculosis in 1927 was the lowest the city ever had. The *Journal of the American Medical Association* points out that a review of health conditions in the State of Illinois for the last seven years indicated that the deaths from tuberculosis and the infant mortality rate in that state have also decreased about 25 per cent, and Illinois claims that no other state in the union with a population in 1920 of four millions and more has reported an average annual death rate so favourable. Yet there was no health demonstration by the Millbank Memorial Fund in that state.

Eminent statisticians shake their heads sadly over the statistical claims of such propaganda. Allowance must always be made for changing economic situations, for general trends and for the many other factors that should ever be considered. Undoubtedly the Millbank Memorial Fund has exerted a most beneficent influence, nevertheless the report of so short a period cannot be taken as conclusive evidence of the beneficial effects of any one agency in any one health field."—Editorial, *J Am M Ass*, Aug 25, 1928

Fatal automobile accidents are assuming more serious proportions every year in Canada. Only two years ago the death rate at the end of August was 48 per 100,000. It is now 72—a rise of 52 per cent in this short time.

"Let every parent remember that there is no greater affliction that can be thrust upon a child than that of inheriting the type of parent who refuses to let him grow up."—*Health Bulletin*, Toronto, 1928, viii, 2

Abstracts from Current Literature

MEDICINE

The Lettsomian Lectures on Rheumatic Heart Disease in Childhood Poynton, F. J., *The Lancet*, 1928, ii, 537, 585, 637

Poynton's work on the etiology of acute rheumatism is too well known to require comment. Anything that comes from his pen on the subject is deserving of careful consideration.

Among the predisposing factors in connection with rheumatic fever he places strong emphasis on heredity and a nervous element, but thinks that there may be other causes related to diet and endocrine disturbances that have not been sufficiently studied. Dampness is less important than climatic changes. The dust of the streets may cause sore throats and thus rheumatism. The "tonsil problem" is not yet settled satisfactorily. While the tonsils, when healthy, must prevent infection, it is hard to be sure just when this function fails and the tonsil becomes a positive danger. And we still have too little information as to the frequency with which rheumatic fever occurs in children who have had their tonsils removed.

One of the greatest difficulties is to know when the carditis, so often associated with rheumatism, comes to an end. Dr. Poynton thinks that, in view of the fact that death rarely occurs during the earliest stages of the disease, and that we know so little as to the method of bacterial invasion of the body in the case of rheumatism, we have insufficient information to decide this question with certainty.

The lecturer still holds, as he did twenty-five years ago, that malignant endocarditis will give the clue in the matter of causation. He thinks, also, in harmony with his well-known views regarding the etiological relationship of a streptococcus in rheumatism, that malignant endocarditis is due to a fulminating infection with the primary organism, and is not secondary.

If mitral stenosis of rheumatic origin could be prevented in the young the after history of rheumatism would be much less terrible. Dr. Poynton has not found that vaccines and sera are of value in the treatment of malignant endocarditis of rheumatic origin.

In regard to the medicinal treatment of acute rheumatism Dr. Poynton deprecates the use of large doses of salicylate of soda in weakly children. Tolsyn, a cinchonic acid preparation, is preferable, as it is without toxic effects. This is a valuable addition to the short list of drugs that can influence the rheumatic infection. The results of sanatorium treatment giving prolonged rest in heart cases have proved encouraging.

Chronic Non-valvular Disease of the Heart

Christian, H., *J. Am. M. Ass.*, 1928, xci, 549

This article has to do with cases with heart symptoms in which there is no evidence of disease of the endocardium or pericardium. The heart may or may not be enlarged. There may be no demonstrable lesion of the myocardium, even where the death is from cardiac failure. There may be signs of recent degeneration, but not of anything of long standing enough to cause the cardiac inefficiency present. Small foci of infiltration may also be discarded, widespread fibrosis is occasionally found as is the fibrosis following an infarct.

The disability is entirely from inefficiency of the heart muscle. Most of the patients are more than 40 years of age. Is the disturbance in the heart muscle functional? Electrocardiograms do not throw any more light on the question. A possible explanation is myocardial exhaustion, which is present after infections or debilitating disease has caused some change.

There are patients with hearts that are upset by slight exertion, who feel respiratory distress, pressure over the heart area, and in whom the heart rate is easily accelerated. There may be extra systoles. This condition resembles cardiac asthenia, but is more curable. Rest and assurance usually are helpful, above all the patients must not be allowed to think that they have heart trouble.

Between this class and the cases with extensive fibrosis of the cardiac muscle there is a large group, usually past forty years, in which hypertrophy of the heart is the only sign, and this hypertrophy seems to be the chief cause of trouble. It is possible that the cause of the hypertrophy is one or more minor infections unnoticed because of their mildness. Cardiac hypertrophy almost always has a grave prognosis, as it indicates a progressive heart lesion. Cardiac arrhythmias do not play an important part in these cases. On the other hand, many of these cases are diagnosed asthma, chronic bronchitis, nephritis even, when the urine is decreased and shows albumen, all because the cardiac enlargement, being the only evidence of heart disease, is not easy to demonstrate. A therapeutic test with digitalis would establish the diagnosis easily. Digitalis is of great help in all these cases, clearing up the dyspnea, edema, etc. The type of chronic myocarditis which follows hyperthyroidism should of course be regarded from the point of view of prevention. Even after auricular fibrillation has developed thyroidectomy may effect a cure.

The author closes with a reference to cardiac dilatation, which he considers so rare a condi-

tion, apart from hypertrophy, that he is not sure the term should be used at all

P. M. MACDONNELL

Ueber die Bedeutung der Epithelkörpervergrößerung bei der Ostitis fibrosa generalisata Recklinghausen (On the significance of enlargement of the parathyroid bodies in regard to osteomalacia) Gold, E, *Mittel aus d. Grenzgeb. der Med u. Chir.*, 1928, xli, 63

The author describes a case of Recklinghausen's generalized fibrous osteitis, otherwise osteomalacia, from v. Eiselberg's clinic in Vienna, occurring in a woman of fifty-four years. A benign adenomatous tumour of the right upper parathyroid gland was removed. Six months later, the patient was found to be much improved in health generally, experiencing a return to vigour and exhibiting a gain in weight of 11 kilos. Previously to operation the blood calcium had been increased 30 per cent, after, it had sunk to normal. The calcium elimination by the urine, which before operation had been more than double the normal amount, was now reduced to one-third normal. This observation affords an interesting illustration of the importance of the parathyroids in connection with the calcium metabolism, this being probably a case of hyperparathyroidism.

A. G. NICHOLLS

La Vaccination Préventive de l'homme contre la fièvre dite ondulante (Preventive vaccination in man against undulant fever) Roziès, H, *Le Progrès Médical*, 1928, xxxix, 1583

The author refers to the pioneer work of Nicolle and Conseil in establishing on a scientific basis and beyond dispute the value of vaccination in the prevention of undulant fever or Malta fever, both by the subcutaneous and the alimentary avenues. Three vaccines used by subcutaneous injection are referred to: (1) the English vaccine, Eyre's modified type, (2) Nicolle and Conseil's vaccine, and (3) the vaccine of Ranque and Senez. The author concludes that the available evidence is insufficient to warrant a definite appraisal of the value of the first-mentioned vaccine.

Nicolle and Conseil's vaccine consists in a mixture of *Br. melitensis*, *para*, and *Br. abortus*. It was originally given twice, at weekly intervals, in doses of 900,000,000. Later 800 to 1,000 millions were given by three injections. The efficiency of their vaccine has been definitely proved.

The vaccine of Ranque and Senez is composed of *melitensis* treated with iodine. Three injections are given at intervals of five to seven days in amounts of 500, 750, and 1,000 millions respectively. Insufficient investigation has been carried out to establish the value or otherwise of this vaccine. The article gives the arguments

for and against the buccal route in the attempt to produce immunization.

The author concludes that there is no doubt as to the efficacy of the subcutaneous method of vaccinating against Malta fever, and this is to be preferred. He quotes Professor Renon as follows: "We may accept both methods. Vaccination by injection when we can, because the results are known and sure. When this plan is not possible it is our duty to use the enterovaccine by the gastro-intestinal route."

SURGERY

Acute Intestinal Obstruction Due to Impacted Gall Stones Powers, J. H., *Surg., Gynec. & Obst.*, 1928, xlvii, 416

Intestinal obstruction due to gall stone is by no means rare, and the four cases reported in this contribution occurred in 179 patients operated on for intestinal obstruction at the Peter Bent Brigham Hospital, Boston, Mass.

The mechanism by which gall stones reach the gastro-intestinal tract is that the process begins with cholecystitis and cholelithiasis, followed by ulceration, erosion, and pericholecystitis. Adhesions form between the gall bladder or ducts and the surrounding viscera, perforation occurring within the adhesions. By far the largest number of perforations occur between the gall bladder and duodenum, but fistulae have been found between the gall bladder and the stomach, jejunum, ileum, colon, and urinary bladder, as well as between the common duct and stomach or duodenum. Perforations may occur without any attending symptoms, as in a case reported by Reimann and Bloom. Approximately one-half the patients recover without operative aid, the stone being gradually passed onward through the bowel. In Wagner's series, 93 passed the stone by rectum, 159 were operated on, and 82 died without operation.

Martin states "the diagnosis of gall-stone ileus is seldom made with certainty", but Murphy, on the contrary, believes that "ileus due to a gall stone which has perforated through the gall bladder into the intestine may have no preceding jaundice but the inflammatory symptoms which accompany such a perforation ought to suggest the diagnosis."

Subcutaneous and intravenous administration of salt solution before operation forms a very important adjunct in treatment, thereby correcting the alkalosis of intestinal obstruction. It is advisable to remove the stone through a transverse incision in order to avoid such constriction of the intestinal lumen as occurs when a longitudinal incision is closed and inverted.

Multiple Polyposis of the Colon Hullsiek, H E, *Surg, Gynec, & Obst*, 1928, LVII, 346

A single polyp of the colon is not a rare occurrence, neither are multiple single polyps in the same bowel uncommon. Areas of polyposis, which are the result of ulcers, strictures, carcinoma, or other mucous membrane irritation, are frequently encountered, but the type of polyposis occurring in young people, in which normal mucosa is replaced by countless small tumours is not of common occurrence. Erdmann and Morris termed this latter form "adolescent, congenital, disseminated polyposis."

Lockhart-Mummery classifies adenomata in the bowel as (1) true, (2) polyps associated with hyperplastic tuberculosis, (3) multiple polyps associated with old stricture, (4) a polypoid condition resulting from ulcerative colitis. Erdmann and Morris classified on a clinical basis (1) the adult acquired type, and (2) the adolescent, congenital, disseminated type. The congenital form becomes evident in childhood or youth, is often shown in other members of the same family, and has a high malignancy incidence.

Fifty per cent occur between the ages of 15 and 35 years and Cripps saw three cases in the same family. In the series studied by the author 53 per cent were males and 47 per cent were females. A definite hereditary tendency was noted in 13 cases, or 11.1 per cent. The area most commonly involved is the rectum and colon representing 41.8 per cent. Lockhart-Mummery states that "almost all recorded cases of multiple polypi of the colon eventually become malignant." The mortality rate was 47.2 per cent.

The surgical treatment, if adopted, varies from appendicostomy to complete removal of the colon. Erdmann in discussing the treatment of the condition is quoted as follows: "One may sum up the present status of treatment of this condition by saying that the only method which holds out any hope for cure in the disseminated variety is one imposing upon the operator great technical difficulties, upon the patient great danger, and upon both the possibility that a successful operation may prove fruitless because the operator has been unable to determine accurately the extent of the process and has, therefore, left behind areas capable of transmitting all the original potentialities of the disease."

The conclusions arrived at by the author are as follows: (1) There are two distinct types of polyposis acquired and congenital. (2) Multiple polyposis is most common in childhood and youth, the average age in this entire series being 30.9 years, with more than 65 per cent occurring before 35. (3) The symptoms usually persist for a long time before medical attention is sought. (4) Males and females are affected about equally. (5) There is a definite hereditary

tendency. (6) The mortality is high, 47.2 per cent under all forms of treatment. (7) The treatment is not yet standardized.

R. V. B. SHIER

Trauma as a Factor in Acute Appendicitis Bissell, A H, *Arch of Surg*, 1928, LVII, 672

From a medico-legal standpoint it seems to be generally considered that injury is never a factor of any great importance in giving rise to acute appendicitis, and consequently compensation is usually withheld in cases of this nature. There is, however, evidence to show that trauma may play an important rôle in determining the onset of acute appendicitis. Von Neumann stated the incidence of such cases to be 6.6 per cent and several others have reported cases of traumatic appendicitis. Deaver's view is that whenever appendicitis occurs as the result of injury it will be found that the appendix shows previous disease, such as foreign bodies, concretions, strictures or adhesions, which do not necessarily cause symptoms in themselves.

It has been shown experimentally that pressure on the abdominal wall can force the contents of a full cæcum into the appendix. It is logical to assume that a blow can do the same thing and if the conditions of disease mentioned are present the consequent rupture of the appendix is quite conceivable. Any increase in the diameter of the appendix gives rise to three times as great an increase in its circumference.

It is not necessary to assume that a sudden high pressure in the appendix will cause a perforation. There may be intermediate stages of damage such as tears of the mucosal lining, or a concretion may be forced into the tip and cause ultimate necrosis.

Dr Bissell reports four cases in support of his contention. Each of these had been in good health and had had no previous abdominal symptoms. There was in each case a history of severe trauma, such as a fall, or a kick, with immediate abdominal pain, nausea, and vomiting. The symptoms were continuous up to the time of operation. In each case the appendix was found to be perforated opposite the mesentery, and in each case faecal concretions were found either in the appendix itself or in the pus surrounding it.

H. E. MACDERMOT

Sur Un Signe Radiologique des Perforations d'Ulcères Gastriques ou Duodénaux. (On a Radiological Sign of Perforation of Gastric or Duodenal Ulcers) Du Pasquier, G., *Révue médicale de la Suisse Romande*, 1928, LVIII, 785

The diagnosis of perforation in the case of peptic ulcers is usually easy. Yet cases arise in which careful clinical examination leaves the

physician in doubt, a doubt that is the more distressing since the time for successful intervention is necessarily short. In cases of doubt operation is better than delay, but, of course, this procedure is not devoid of danger nor of other objections. Hence the importance of an early precise diagnosis.

One of the diagnostic signs of perforation of one of the abdominal viscera that is most often spoken of is a diminution or disappearance of the liver dullness. This is due to the escape of air into the upper zone of the abdomen below the diaphragm. Unfortunately, this sign is not invariable.

X-ray examination usually reveals a collection of gas below the diaphragm, as Assmann, Vaughan and Biams, and Biams and Meyer have shown. This observation is confirmed by Du Pasquier. The picture is very typical. It shows a clear crescent, more or less dense, according to the amount of gas that has escaped, the convexity of which is formed by the diaphragm and the concavity by the liver. The diaphragm itself is seen as a thin dark band, well defined, which separates the collection of air from the clearness of the neighbouring thoracic cavity. The crescent is best seen on the right side, being somewhat obscured on the left by the stomach. The author considers this to be diagnostic and reports three cases in which an accurate conclusion was reached through radiological methods. He does not advise repeated X-ray examinations under the circumstances, nor should the patient be moved to the X-ray department.

He concludes that a rapidly conducted radiological examination does not aggravate the condition of the patient, even when he is extremely shocked, but does not think that operation should be unduly delayed in order to permit of the attendance of the radiologist.

A. G. NICHOLLS

OBSTETRICS AND GYNÆCOLOGY

Die Puerperal Sepsis (Puerperal Sepsis)

Schottmüller, H., *Munchener med Wchnschr*, 1928, lxxv, 1589, 1634

This article discusses very fully and scientifically the subject of puerperal sepsis, which is occupying so much attention at the present time. It begins with a historical retrospect and then goes into the etiology, particularly in regard to the micro-organisms that may be at fault. The pathology is also dealt with at some little length, including the sequelæ and complications. Professor Schottmüller thinks that puerperal infection falls into two groups, corresponding to wound-infection and wound-intoxication. The former may be due to a variety of pathogenic micro-organisms, of which the streptococcus is

the commonest and the most virulent, the latter, due to putrefactive germs (saprophytes).

In the matter of treatment the author lays stress upon the following points. When too little fluid is being ingested drip enemata of 10 per cent glucose solution should be administered. If the patient is very anæmic blood transfusion of from 500 to 800 cc is indicated. In cases due to infection with hæmolytic streptococcus injections of blood from persons convalescing from the same type of infection should be tried, in the hope of providing the necessary antibodies. For failing heart strophanthin should be given, and Schottmüller thinks that adrenalin intravenously is of benefit, though this remedy has of late been somewhat overlooked. Antipyretics are of no lasting value, nor are the newer antiseptics of use, such as, collargol, electargol, optochin, argochin, argoflavin, and typhalavin. Schottmüller does not think it possible to attain "internal disinfection." Vaccines and sera he has not found of value in infections so acute as the puerperal form, nor is non-specific protein therapy reliable. Curettage of the uterus, to clear out fetal remnants, is recommended, provided that the os is dilated. This procedure is safer than manual removal. It is seldom that surgical intervention is called for, for the reason that it is not often possible to localize and deal with suppurative foci. Only two indications exist for extirpation of the uterus: (1) gaseous phlegmon of the uterus, or puerperal tetanus, and (2) septic thrombophlebitis.

In the important matter of prophylaxis, while admitting that infection may be introduced from without, Schottmüller is of the opinion that the danger is greater from within, i.e., from micro-organisms present in the vagina before labour. He emphasizes the necessity of ensuring, after the termination of labour, that the uterus and vagina be free of debris and blood clot. Many cases of puerperal sepsis are, moreover, to be attributed to criminal practices in the earlier months of pregnancy.

A. G. NICHOLLS

PÆDIATRICS

Tetanus Neonatorum Smith, D. L., *Arch Pæd*, 1928, xlv, 562

A child ten days old had developed spasms and stiffness of the jaws on the third day. The spasms gradually became generalized, convulsions occurring every day, there was some fever, but no vomiting. The baby would not nurse and refused feeding with a spoon.

Examination showed the child to have trismus and marked retraction of the neck. Muscular spasms were easily incited by handling the baby. The navel was red and with a discharge of bloody pus. The temperature was 101.5.

On admission to hospital the child was given 1,500 units of antitetanic serum with ten minims of magnesium sulphate (50 per cent aqueous solution) intramuscularly. The anti-toxin and magnesium sulphate were repeated the next day, together with five grams of chloral hydrate in water given by rectum every four hours. The child was much quieter in the day but still had some trismus and marked opisthotonos. There was marked improvement in the next three days. The magnesium sulphate hypodermically seemed to relieve the spasms brought on by feeding, which constituted a most troublesome feature. The formation of excessive mucus was checked by atropine gr 1/900, given every four hours and the cyanosis and dyspnoea were relieved by caffeine sodium benzoate, 1/2 gr given hypodermically after each feeding.

The child gradually improved and was discharged after twenty-three days, perfectly well. The tetanic symptoms subsided slowly, and it was frequently necessary to give some form of stimulation after feeding on account of the cyanosis and weak pulse which the act brought on. The caffeine sodium benzoate seemed to be sufficient for these and epinephrin 5 minims was also used with good effect. Otitis media also occurred as a complication, but it cleared up on opening of the ear drums.

The case is worthy of notice on account of the high mortality attending the condition. The note is made that a case of tetanus had occurred in the same house two years previously.

PATHOLOGY

Multiple Primary Neoplasms in Lower Animals

Feldman, W. H., *Am J Path*, 1928, iv, 497

The occurrence of one or more primary tumours in the human subject is not uncommon and has been the subject of a fair number of articles. In the lower animals the observation is much rarer, chiefly owing to the fact that most of them do not have such long lives as man, especially, of course, is this the case with those species that are used for food. It is well-recognized now that the lower animals may be affected by the same kinds of tumours that are found in man, and there is no obvious reason why new growths should not be multiple in them, except for the reason just mentioned. References to this phase of the matter are rare in the English literature.

Feldman reports the case of a thirteen-year-old male shepherd dog who was the subject of the following neoplasms, recurrent squamous-celled carcinoma of the mouth, with metastasis in a regional lymph-node, multiple hæmangiomata of the liver, malignant leiomyoma of the cæcum, papillary cystadenoma of the prostate,

a testicular tumour arising from the interstitial (Leydig) cells, and multiple lymphomatous nodules in the spleen.

The author points out that multiple neoplasms are frequently found in dogs more than ten years old. This suggests the influence of senile retrogression and subsequent tissue involution in the etiology.

A. G. NICHOLS

THERAPEUTICS

Problems in the Treatment of Ascites

Snell, A. M., *Med Clin N Am* May, 1928

The multiplicity of the causes of ascites has been recognized since the time of Galen. Cases presenting this sign fall into two groups, the larger being those in which the underlying disease may be quite easily identified, the smaller, a group in which the diagnosis is an extremely complex problem. Among useful aids in this problem are the liver function tests and the newer diuretics. Ninety per cent of hepatic ascites cases show some retention of dyes—bromsulphthalein or phenoltetrachlorophthalein—a marked retention suggesting primarily a liver fault, while slight retention suggests secondary liver effects from environmental or circulatory changes.

A "therapeutic test" with the diuretics—ammonium salts and merbaphen—may contribute information as to the cause of ascites. A failure of the abdomen to alter in contour following diuresis may indicate encysted fluid or peritoneal thickening. In cases of non-tuberculous polyserositis diuresis gives a welcome substitute for repeated tapings and at times gives prolonged relief. It is thought that a poor response to the diuretics in cirrhotic ascites may indicate a poor prognosis.

The author urges that, in cases of ascites from obscure causes, a careful investigation of cardiovascular and renal systems should be made. Dye tests of hepatic function and serum bilirubin tests should be followed by a cautious therapeutic trial of the diuretics.

Peptone Treatment in Bronchial Asthma

Ramirez, M. A., *Arch Int Med*, 1928, xlv, 368

This paper opens with what the author feels to be the somewhat sweeping statement that no conclusive study of bronchial asthma has as yet been presented. But when we consider how closely the asthmatic state is linked with the problem of anaphylaxis and desensitization, and how confused our knowledge is regarding these latter subjects, the statement becomes more acceptable.

Dr Ramirez then introduces the subject of non-specific desensitization, showing how we have given up the original idea of specific methods, and that now a large number of

protein substances are employed in non-specific therapy, but we still have no sufficient explanation for the success (not always complete) which it has achieved. The substance whose employment is considered in detail in this paper is peptone. It would be logical to expect that the chemical constitution of the particular brand of peptone used would have a definite and characteristic influence, but a review of the opinions of various workers shows that they differ greatly on this point. Auld, who is one of the chief supporters of peptone therapy obtained unfavorable results with Witte's peptone owing to its histamine content, but other workers found that even with the preparation suggested by Auld the results were disappointing, and even dangerous. The method of administration also varies with different workers, some give it by mouth, some intravenously, some intradermally and others subcutaneously, and whereas some claim good

results with the latter, others insist on the intracutaneous route being the better, since it is claimed that sloughing will be produced by subcutaneous injections.

Dr Ramirez has employed the various preparations of peptone and the various ways of administering it, in a series of 60 cases, and from the results obtained he concludes that this substance is of no value in bronchial asthma. In 40 cases the peptone was given either intramuscularly, intradermally or by mouth. No effect at all was noted. In ten more cases it was given intravenously, one c.c. of a 5 per cent solution twice a week for four weeks, in half the cases, and 2 c.c. once a week for four weeks in the other five. Slight improvement only was noted. In ten other patients Auld's method of intravenous injections was followed, but no success was obtained.

H. E. MACDERMOT

Obituaries

Dr Donald Booth Holden, of Victoria, B.C., was a passenger on the ill-fated plane on which he was crossing to Seattle to meet Mrs. Holden, who was on a holiday visit with her son Pilot Alec B. Holden, chief of the Tacoma Air Port Station. Many passengers had been carried to Vancouver and Seattle and everyone had enjoyed the safety and riding comfort of this new service, but August 25th was foggy and that, combined with the smoke of forest fires, was apparently the cause of low flying and contact with the water near Port Townsend, half an hour after leaving Victoria. The impact with the water was severe enough to have brought sudden death to the passengers. Dr. Holden's body was recovered and was cremated.

Dr. Donald Booth Holden

Dr. Holden was born in Belleville, Ont., sixty-two years ago. When he was four years old the family removed to Montreal. He was educated at McGill University, where he graduated with the B.A. degree in 1889, and M.D., C.M., in 1891.

For thirty-seven years, Dr. Holden practised in Victoria, and at the time of his death was one of the senior members of the medical profession in that city in point of years of service. He was a hard worker, cheery, and bright withal, retiring, but to those who knew him best, he was possessed of a kindly heart and a cool calm courage which never failed him or his patient in emergency. Dr. Holden took a keen interest in his profession and upheld the best traditions of practice in his relations with his colleagues and patients. He was a member of the Victoria, British Columbia, and Canadian Medical Associations, a member of the Union Club, the Yacht Club, and Colwood Golf and Country Club. His beautiful home and gardens at "Beresford" provided pleasurable relaxation during the past few years. A memorial service was held on September 26th at Christ Church Cathedral, which was attended by members of the Victoria Medical Society, graduate nurses and the pupil nurses from both the St. Joseph's and Jubilee Hospitals.

Mr. A. R. Holden, K.C., of Montreal, a member of the law firm of Meredith, Holden, Heward, and Holden, and Mr. R. C. Holden, of Westmount, Que., are brothers.

To Mrs. Holden and family the sympathy of the whole profession is extended and we trust that the esteem in which her late husband was held will be a comfort in this hour.

Dr. Samuel Allison, one of the oldest residents of the County of Peel, died in Caledon East on October 1st in his ninety-fifth year. Born near Dixie, Dr. Allison had come to Caledon East as a young man, and had practised there for more than fifty years. He was a graduate of the old Victoria School in 1862.

Dr. F. J. Ball. On September 17th the members of the medical profession and the citizens of Regina

were also deeply moved on hearing that one of their most honoured members had passed away in the person of Dr F J Ball. Although he had been ill for the past month, still the hope that he would be around again was ever cherished by friends who grieved the more when the hand of death made all efforts futile.

The esteem to which he had attained was exemplified on the day of his funeral when his body lay in state at Knox Church surrounded by a bank of flowers, a tribute from those who knew him and those whom he had attended. With flags at half mast in the city, with six of his intimate friends as pall bearers and six of the medical profession as honorary pall bearers attending, he was given a Masonic burial in the family plot.

Dr Ball was born in 1865 at Rigby, Ontario, obtained his M.B. degree at Toronto University in 1893, and his M.D., C.M. at Trinity. He practised at Singhampton, Ontario, for twelve years, after which he went abroad and studied under some of the most eminent members of the medical profession, during which time he obtained his M.R.C.S. England, and his L.R.C.P. London. He was granted his F.A.C.S. in 1924. On return to Canada in 1907 he settled in Regina and built up a very extensive practice. In 1912 he limited his practice to consultations and surgery, and as such continued up to the time of his recent illness.

His professional bearing, kindly actions and friendly advice ever endeared him to the medical men with whom he came in contact, and won for him whatever honours they were able to bestow.

That he had not retired some years ago leads one to say that he practised his profession for the love of it rather than for financial gain. Dr Ball leaves a wife and two sons to mourn his loss and the sympathies of the whole medical profession is extended to them. S E MOORE

Dr James Henry Duncan, of Chatham, died on September 22nd in his 78th year, following an attack of pneumonia. He was born in England but came to this country when four years old. He graduated in medicine from the University of Toronto in 1881 and settled in Chatham in 1884.

Dr Duncan was one of the few remaining physicians of the old school—the family physician of the last generation—and was an active member of the medical societies and a familiar figure in all the gatherings of the profession.

Dr Duncan leaves one daughter, Dr Jean Renwick Duncan.

Dr Charles Hector Godin, Superintendent of Marine Hospital Service for the Department of Health, and a prominent member of the medical profession died on September 24th, 1928. Dr Godin, who was 56 years of age, had been ill for the past two months. He was widely known, his duties as Superintendent of Marine Hospitals taking him from coast to coast. For twenty-two years he was a member of the civil service, having been appointed by the late Hon L P Brodeur to the Department of Marine and Fisheries, and later transferring to the Department of Pensions and National Health, when the Marine Hospitals' service was transferred to the latter branch of the civil service. Dr Godin was born in Montreal, educated in the Montreal parochial schools, and also at Sherbrooke College, later entering Laval University, from which he graduated with honours in 1893. After practising his profession in L'Ange Gardien and Farnham, Que., he later returned to Montreal, and in 1906 he was appointed to the position in the civil service which he occupied for so many years.

Dr R. Leprohon. The death of Dr R. Leprohon, well known in French Canadian medical circles, occurred on September 20th, 1928, after a lengthy illness. He was born in St Charles, Que., on April 17, 1855. After completing his early studies he entered Bishop's College, where he graduated. Dr Leprohon practised in the United States and on the Gaspé coast. In 1922, because of ill health, he returned to Montreal.

Dr Neil MacPhatter, of Calgary, passed away on Monday, October 8th, 1928, after a very long illness, having been confined to his room for over a year. He was in his 79th year and graduated from the Royal College of Edinburgh, in 1881. Prior to registering in Alberta in 1922 he practised for many years in New York City.

Dr J J McDermott died at Massey on September 12th, in his forty-fourth year. He was born in Ireland, came to Canada with his parents at the age of four, and received his education in Kingston, graduating at Queen's University. For many years Dr McDermott was with the Spanish River Lumber Company, but retired later to a practice of his own at Sudbury. Dr McDermott was not only active in practice but had been keenly interested in matters both religious and political.

GREAT BRITAIN

Darwin and Downe House

Downe House, in which Charles Darwin lived for nearly forty years, is now a gift to the nation, entrusted to the British Association for the Advancement of Science. More than a quarter of a century ago, Andrew Carnegie thought of buying it and putting up a sum of money to settle, as he phrased it, one way or another, the question of evolution. But those whom he consulted felt bound to advise him that, as a business proposition, the idea was unsound. Later on Sir Arthur Shipley, Master of Christ's College Cambridge, where Darwin had passed his undergraduate career, urged that some way should be found of making Downe House a national possession. But the times were unpropitious. A few years ago

Professor H F Osborn of New York, again propounded a scheme for transforming Darwin's home into an endowed centre for evolutionary research, and suggested that part of the funds might be supplied from America if the Royal Society would adopt and develop the idea. The Council of the Society, after friendly and detailed consideration, came to the conclusion that a very large sum of money would be required to transform a comparatively small country house into a research institution and to provide for its staff and maintenance. Even if the sum were available it could be spent to greater scientific advantage in the development of some of the existing research institutions. At Leeds last year Sir Arthur Keith, then President of the British Association,

issued an appeal, with the authority of the Council, for the more modest object of preserving Downe House simply as a memorial of England's greatest naturalist.

The appeal had a swift and fortunate response, for Mr Buckston Browne, a distinguished London surgeon, offered to buy the house, provide funds for its maintenance, and make it a gift to the nation in the custody of the British Association. With the generous co-operation of the Darwin family, the end has been achieved and the house and the eighteen acres in which it stands are now vested in the British Association. Some of the actual pieces of furniture used by Darwin in his study have been presented by the family, and Mr Buckston Browne is collecting other pieces of the same period so as to reproduce as closely as possible the actual environment in which "The Origin of Species" and many other great books were written. All the editions of Darwin's books are being got together, and as soon as the lease can be required from the present tenants Downe House will be opened to the public. There is a superstition that the aura of evil deeds lingers in the promises in which they were committed. If there be no supernatural vestige left by great men, at least our imagination is quickened and our sympathies attuned to gracious memories by seeing the simple surroundings in which they thought and worked. The rooms in which Darwin wrote, the garden paths on which he paced, and the simple green houses in which he conducted his experiments, if only because they are homely and undramatic, can make us realize the possibilities of human achievement. For those patience and genius, the most faithful devotion to pedestrian fact, and the most daring imagination combined to bring about a stupendous revolution in human thought. Access to Downe House will preserve for all time the inspiring personality of the man who in the words of Mr Punch's inspired epitaph, was "Recorder of the long Descent of Man, And a most living witness of his rise."

—The Weekly Times, Sept 1928

Sir Horace Darwin

The death is announced, at Cambridge, of Sir Horace Darwin, son of Charles Darwin, and a great inventor and perfecter of scientific instruments. Horace Darwin was born at Downe on May 13, 1851, the fifth son of Charles and Emma Darwin. He was educated at Trinity College, Cambridge.

Immediately after he had taken his degree, Horace went to the works of Messrs Easton and Anderson, an engineering firm of high repute, and served his time as an apprentice. It was at this time that he designed his first scientific instrument, a kymograph for recording the rate of growth of small plants.

On his return to Cambridge he became interested in the work that the late Mr A G Dew Smith was doing for the late Sir Michael Foster. Foster, who had recently been appointed to the Chair of Physiology, wished to equip the laboratory with apparatus and found that, practically without exception, all the instruments required for following up the recent work on nerves, blood pressure, etc., had to be imported from the continent. He interested his friend Dew Smith, a rich amateur, who invited the co-operation of Horace Darwin, and together they started to produce instruments which were at least equal, and in many cases superior, to those of continental manufacture. A little later Darwin designed for his cousin, Sir Francis Galton, the series of anthropometric instruments with which so much of Galton's work was performed. With his brother, Sir George Darwin, he designed the bifilar pendulum form of seismograph for recording very small seismic disturbances. The rocking microtome was scientifically the most important instrument designed by Darwin. It was the outcome of the work of several men.

A few years before the outbreak of the War he was made a member of the Advisory Committee on Aeronautics, appointed to advise the government what researches should be made to develop the science of flight. He devoted all his energies to designing instruments for the new conditions introduced by air warfare. He was always ready to discard an idea of his own if he felt that the other man's design was better than his. Sir Horace married in 1880 the Hon Emma Cecilia Farrer, daughter of the first Lord Farrer, and leaves two daughters.

Street Noises

At a joint council meeting of the People's League of Health, held at 12, Stratford place, London, on July 12th a resolution was passed—

"That in view of the fact that eminent neurologists and mental experts have emphasized the grave effect on the nervous system of noises which tend to increase the incidence of functional mental and nervous disorders in our midst this meeting urges upon the People's League of Health the desirability of calling attention of the government to the need for the control and diminution of preventable noises in our streets, and asks that the subject shall receive the serious attention of the Ministry of Health."

A letter embodying this request has been forwarded to the Minister of Health, who has been asked to receive a deputation consisting of Sir Farquhar Buzzard, Sir Maurice Craig, Sir Robert Armstrong Jones, Sir James Purves Stewart, Dr A P Tiedgold, Prof G Robertson, and Dr Thomas Beatson.

Sir Arthur Keith, Hon FRFCS

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow, held on September 3rd, the honorary Fellowship was conferred upon Sir Arthur Keith, MD, FRS. During the course of an "at home" given in the Faculty Hall to members of the British Association for the Advancement of Science, Sir Arthur Keith signed the roll of honorary Fellows. It will be recalled that last year Sir Arthur Keith was President of the British Association, and the subject of his address was "Darwin's theory of man's descent as it stands today."

The Medical Research Council

By an Order of the Committee of the Privy Council Professor Robert Muir, MD, FRS, Sir John Herbert Parsons, FRS, FRCS, and the Right Hon Sir Charles Philips Trevelyan, Bt, MP, have been appointed members of the Medical Research Council, filling the vacancies caused by the retirement of Professor Georges Dreyer, Sir Archibald Garrod and the Right Hon William Graham, MP. The new appointments became effective on October 1st.

The Bernhard Baron Trust

Mr Bernhard Baron has by deed transferred the sum of £375,000 four per cent Consolidated Loan to trustees for the foundation of a trust to be called "The Bernhard Baron Trust for Hospitals and Asylums for Orphans and Crippled Children." It is provided that during the next twenty years the total amount available for distribution shall be approximately the same each year, and the trustees shall in every year apply such part of the capital and income of the fund as they deem fit for the benefit of hospitals of various kinds and homes and institutions for the care of orphaned and crippled children. The money available is directed to be applied in the proportion of 75 per cent among Christian and undenominational hospitals, homes, and asylums, and 25 per cent among similar institutions under Jewish control. The Marquess of Reading is nominated chairman of the board of

trustees, and the annual distribution will take place on December 5th of each year, which is the anniversary of the donor's birthday.

The Rockefeller Foundation and Cambridge University

The International Education Board of the Rockefeller Foundation has offered the sum of £700,000 for certain new developments in the Departments of Physics and Biology of Cambridge University. The amount mentioned includes a contribution of £250,000 for the proposed new University Library. Plans for this building have been prepared by Sir Giles Scott

provisionally, and the cost for building and maintenance has been estimated at £500,000. The condition attached to the Board's offer is that the University shall raise the balance of the amount necessary to complete the whole scheme. For this purpose a balance of £229,999 is required.

The retiring Vice-Chancellor, the Rev G. A. Weeks, Master of Sidney Sussex College, in announcing the offer, said, "If the University is able to accept this splendid offer of assistance, not only will the whole cost of building the new library and providing for its maintenance be met, but a new and magnificent opportunity of advancing the physical and biological sciences will be put into our hands."

NOVA SCOTIA

At the annual meeting of the Eastern Counties Branch of the Medical Society of Nova Scotia which was held at Antigonish in August last, the President, Dr M. E. McGarry, of Margaree, was in the chair. The afternoon of the first day was given up to papers contributed by Drs Murphy, Mack, and K. A. MacKenzie, of Halifax, and Dr W. F. MacKinnon, Antigonish. Members and guests were entertained at dinner by the president, after which the presidential address was delivered and a business session was held. The morning of the second day was given over to clinics at the St. Martha's Hospital. The officers elected are: Honorary President, Dr George E. Buckley, Guysboro; President, Dr O. R. Stone, Sherbrooke; Vice-presidents, Drs R. F. MacDonald, Antigonish, and H. C. S. Elliott, Guysboro; Secretary, Dr P. S. Campbell, Port Hood.

At a meeting of the Cape Breton Branch of the Medical Society of Nova Scotia, held at the General Hospital, New Waterford, on September 14th, a resolution was passed favouring the use of toxoid as a preventive of diphtheria. It is planned to immunize the school children of Sydney against diphtheria by this means. The meeting at New Waterford was addressed by Dr Samuel Bell, of New York, who spoke on "Asthma."

Medical men figured quite prominently in the provincial elections held on October 1st. Four of the Conservative, and eight of the Liberal candidates were physicians. Those who offered in the Conservative interests were Hon. Dr W. N. Rehfuss (Lunenburg), Hon. Dr B. A. LeBlanc (Richmond), Dr H. A. Grant (Victoria), and Dr A. MacD. Morton (Halifax). The Liberal candidates were Drs J. L. McIsaac (Antigonish), T. I. Byrne and W. J. Kennedy (Halifax), J. W. Reid (Hants), James A. Proudfoot and M. E. McGarry (Inverness), and W. R. Dunbar and D. L. MacKinnon (Colchester). Of these, Drs Morton, McIsaac, Proudfoot, and McGarry were elected. The dental profession was represented in the contest by Dr M. E. Morrison, Liberal, (Gt. Sydney), who is one of the successful candidates.

Delay in the reconstruction of the Highland View Hospital, Amherst, has been occasioned by the necessity of obtaining the consent of the citizens to the borrowing by the town of \$40,000.00 to supplement money already on hand. This consent has now been obtained, the plans for the new structure have been accepted, and work has been commenced. A large part of the walls of the old buildings are being utilized, but the interior has been replanned. The reconstructed hospital will accommodate fifty-two patients. Seventy thousand dollars will be expended on the building and twenty thousand in

furnishing it. Pending the completion of the hospital building, the training school for nurses has been disbanded. The work of the hospital is being carried on in houses built for residences, and it was found impossible to suitably accommodate the pupil nurses in the quarters available for them.

Dr Eva W. Mader, who, since her graduation at Dalhousie in 1927, has been on the medical staff of the Nova Scotia Sanatorium, Kentville, has been awarded a Connaught fellowship in the School of Hygiene, University of Toronto. The fellowship is of the value of \$1,500.00. Dr Mader intends to proceed to a degree in Public Health. She is a daughter of Dr A. L. Mader, and a sister of Dr Victor Mader, of Halifax.

On the twenty-fourth of August, Dr W. Sidney Gilchrist (D.M., '27), was designated as a medical missionary by the Pictou Presbytery of the United Church of Canada. The ceremony took place at Pictou, Dr Gilchrist's home town. He has been assigned to Angola, West Africa. Dr and Mrs Gilchrist will spend a year in Portugal, learning the language of Angola, before proceeding to their mission field.

John D. Winelose, who poses as a faith healer, is under arrest at Arichat, charged with an offence against a feeble-minded girl who had been under his treatment for epilepsy.

Action brought by the Federal Department of Health against Rivers Hicks, of Kentville, resulted in the imposition of the minimum fine of \$25.00 and costs. Hicks has been advertising and selling a "cure" for cancer, which, on analysis, was found to be only carbonate of potassium. The charge brought against him was that of selling drugs misbranded, contrary to the provisions of the Drugs Act.

Dr M. R. Young, of Pictou, recently had a narrow escape from drowning. He had crossed the harbour in a motor boat in response to a sick call, and on attempting to board the boat for the return trip he missed his footing and fell into deep water. The doctor does not swim, and, as it was dark at the time, those in the boat had some difficulty in locating and rescuing him.

Dr Victor Mader, of Halifax, recently went by aeroplane to Sheet Harbour, to connect there with a Dominion Government ship which had been ordered to proceed to Sable Island and bring a sick wireless operator to Halifax. Dr Mader, who is a member of the Halifax Aero Club, was accompanied to Sheet Harbour by a fellow aviator, who brought the machine back to Halifax, but the doctor piloted the machine to Sheet Harbour and made the landing there.

Dr R M Benvie, of Stellarton, has gone abroad for six months' graduate study in London and elsewhere

Dr C A S McQueen, of Amherst, has returned from a much enjoyed tour of the British Isles and the Continent

Among those who came to their native province for a holiday this summer were Dr Henry Dickson, of Hilo, Hawaii, and Dr J Clyde MacDonald, of Edmonton

A class of nurses graduated from St. Martha's Hospital, Antigonish, on the fourth of September. The graduates were addressed by Dr W F MacKinnon

QUEBEC

The health survey of Montreal, the greatest work of its kind ever undertaken in the Dominion of Canada, was entrusted to men noted in the world of research, men of experience, discernment, precision, and discretion. These men were provided with an adequate and competent staff under the direction of Dr A. Grant Fleming of the Anti Tuberculosis and General Health League. The work has involved diligent enquiry and painstaking scrutiny, covering a period of eight months. It was financed by a group of private citizens desirous of contributing to the welfare of the city. When the Metropolitan Life Insurance Company learned of what was being done in this health survey for the benefit of the citizens the directors expressed a desire to print the report and distribute thousands of copies gratuitously. Life insurance companies have a direct interest in increasing the average of the lives of their policy holders, hence their interest in this life survey.

"The United States and Canada lead the world to day in hospital service," said Dr F H. Martin, Director of the American College of Surgeons, prior to making the official announcement of approved hospitals for 1928 at the opening session of the eleventh annual Hospital Standardization Conference. "This is the conclusion reached after eleven annual surveys of the hospitals of both countries by the American College of Surgeons. The right care of the sick and injured has been the slogan of the American College of Surgeons in this work." To the public the announcement of the approved list of hospitals at this season should be one of extreme interest, inasmuch as one out of every ten will need the right kind of hospital care before this time next year. The best assurance for this is in the approved hospital with its ethical, competent, medical staff, adequate facilities for diagnosis and treatment, and competent supervision over all activities. Eleven years ago only 89, or 12.9 per cent, of the hospitals under survey met the minimum requirements for hospital service, as sponsored by the American College of Surgeons and now universally accepted. To day, after eleven years of effort, 1,919, or 69.5 per cent, have attained a place on the honour roll—the official approved list. Eleven years ago the patient remained in the hospital 20 to 24 days, on the average, whereas to day he remains only 12 to 14 days in the same hospital for the same condition. The American College of Surgeons officially announced that the following hospitals in Quebec have been awarded a place on the Fully Approved or Conditionally Approved List for 1928, thus signifying that they have adopted the basic requirements which insure the best care of the patient.

MONTREAL—Alexandra Hospital, 175 beds, Ouldrén's Memorial Hospital, 130, Homœopathic Hospital, 112, Hôpital Sainte Justine pour les Enfants, 300, Hôtel Dieu de Saint Joseph, 400, le Miséricorde Hôpital, 350, L'Hôpital Notre Dame, 300, Montreal Foundling and Baby Hospital, 96, Montreal General Hospital, Central Division, 400, Montreal General Hospital, Western Division 125, Royal Victoria-

Montreal Maternity Hospital, 808, Shriners' Hospital for Crippled Children, 60, all fully approved

QUEBEC—Hôpital Laval, 260 beds, Hôtel Dieu du Précieux Sang, 252, Jeffrey Hale Hospital, 125, St. François d'Assise Hospital, 100

SHERBROOKE—Hôpital Général St. Vincent de Paul, 300, Sherbrooke Hospital, 89

THREE RIVERS—St. Joseph's Hospital, 101.

For the purpose of schooling their own nurses in obstetrics, a new maternity ward has been opened at the St. Justine Hospital. Formerly, it was necessary for a number of nurses to leave at times to go to the Misericorde Hospital in order to study maternity cases. Dr Gaston de Cotret, formerly of the Misericorde Hospital, assisted by Dr A. Groulx, will be in charge. There will be room in Dr de Cotret's ward for about thirty patients. Dr J C Bernard, Medical Superintendent, stated that the St. Justine Hospital is not changing its policy and admits adults as well as children. "The necessity of giving our nurses a proper training compels us to inaugurate this new section," he said. Since the institution was founded more than twenty years ago, 21,434 children have been admitted to the hospital, 2,437 of whom were treated last year.

The Brehmer Rest Preventorium at Ste Agathe des Monts has had such a successful year that more than half their patients have been discharged this autumn after a complete cure following treatment. The Brehmer Rest is non sectarian, with accommodation for women and children only. Cases of incipient tuberculosis, as well as those recovering from operations and serious illness, are admitted as soon as possible after application is made. The small fee charged by those who can pay does not meet the expenses incurred, but the Preventorium is affiliated with the Federated Charities and, as such, has in many cases carried the whole expense, where a patient is unable to pay. Dr Brehmer founded the first sanatorium in Europe for the treatment of lung disease in 1859 and his name was given to the first Preventorium opened in Ste Agathe in 1913.

That the science of obstetrics should be given more attention by the medical fraternity the world over, and should be regarded as more the work of the general practitioner than that of a specialist, was the opinion advanced by Dr Cyrille Jeannin, Parisian specialist, who arrived here recently to give a course of lectures at the University of Montreal. Dr Jeannin came to Quebec City a short time ago where he lectured at the recent medical convention there. He remained here for another month, then returned to Paris to resume his courses at the Hôpital de la Pitié there. His work here was divided into two sections, clinics and lectures to students in medicine. While here his course was under the auspices of L'Institut Scientifique France Canadien and the University of Montreal. His only public lecture to medical men of Montreal was given at the Cercle Universitaire, the subject being "What is a Doctor?"

The dedication of the Medical Centre in New York, the Diamond Jubilee of the Dalhousie Medical School, and the dedication of the laboratories and hospital of the College of Medicine at Iowa University, are three important medical events that are taking place about this time, and were attended by McGill medical men. Dr C F Martin, Dean of the McGill faculty of medicine represented the university at the dedication of the Medical Centre in New York City, Dr W W Chipman represented McGill at the Diamond Jubilee of the Dalhousie Medical School in Halifax, Dr Campbell Howard will represent the university at the exercises at the University of Iowa, which take place November 15th and 17th.

The 25th anniversary of the founding of the Association of French speaking Medical Men of North America was singularly and brilliantly honoured, at a banquet recently held in the Chateau Frontenac, attended by some three hundred delegates to the Association convention, and a distinguished gathering of civic, provincial and clerical officials. Presided over by Dr P C Dagnean, a prominent Quebec physician and President of the Association, the banquet was featured by an address delivered by the President in which he outlined the progress of the Association, the aims and aspirations of its members, and paid great tribute to the founder of the body, Dr M D Brochu, for his untiring efforts in furthering the ideals of the Association. Dr Dagnean was followed by Dr Brochu himself, who delivered an extremely interesting discourse wherein he outlined the successes and failures of the founders and original members of the Association during the time when the organization was in its infancy, and complimented the executives of the body on the success of the current convention. In reply to Dr Dagnean's toast to the Province of Quebec, following the close of Dr Brochu's address, the Hon Honoré Mercier, Minister of Lands and Forests, and representative of the Government at the gathering, officially greeted the visiting physicians in the name of the Government, and congratulated them upon the advancement in medical science, due mainly to their efforts in the past few years.

The memory of Dr William T G Morton was honoured by members of the Associated Anaesthetists of the United States and Canada in the little Domo Room of the Massachusetts General Hospital in Boston. On October 16, 1846, Dr Morton gave the first demonstration of a surgical operation performed with the use of ether. After a visit to Dr Morton's grave, a bust of the surgeon was presented to the hospital by Dr Francis H McMechan, Secretary general of the Association. The bust was unveiled by Dr William B Howell, of Montreal, President of the Canadian Society of Anaesthetists, Dr Albert H Miller of Providence, R.I., President of the Boston Society, and Dr John H Evans, of Buffalo, N.Y., President of the Eastern Society.

What is described as a fine specimen of African negro art, worth several hundred dollars in the art treasure marts of the world, has been given to the Strathecona Museum of McGill University by Sidney Carter, of Montreal. The gift, which was announced by E L Jndah, curator of the McGill museum, is a wooden mask made by African negroes. The striking thing about it is that the facial features are the exact opposite of those of the negro. A small nose, a small mouth, and small ears set far forward on the side of the skull, are the prominent differences in comparison with the typical negro facial and skull structure.

Dr A. K. Haywood, Superintendent of the Montreal General Hospital, was presented with a testimonial from the Royal Canadian Humane Association at the Rotary Club luncheon on September 22nd, in the Windsor Hotel.

Rotarian Canon Shatford spoke of Dr Haywood's conspicuous deed of heroism in rescuing two women, Mrs. Anne Charette and Mrs L. Clarson from drowning in Lake Manitou, on August 17, 1927. The certificate was presented with all Rotarians standing.

Pædiatrists of Montreal held a clinical meeting on November 7th, under the auspices of the Pædiatric Department of McGill University and the teaching hospitals affiliated with the university. The morning was devoted to conferences and in the afternoon living cases were shown. Luncheon was served in the Royal Victoria Hospital and a dinner held in the evening at the Windsor Hotel.

Specialty bound booklets, containing one of Sir William Osler's famous addresses, "The Way of Life," were presented to the second year medical students of McGill University by Dr A. H. Gordon on behalf of Mrs W Grant Stewart, who presented similar booklets to the second year medical students last year. In a short address Dr Gordon paid a tribute to the memory of the late Dr Stewart by whose bequest the booklets were being given, and briefly reviewed the career of Sir William Osler, one of McGill's most famous graduates and formerly a member of the teaching staff.

We chronicle with pleasure an event of more than local interest when we record that there was unveiled in the University Club of Montreal, on September 26th, a portrait of the veteran physician, Dr A. D. Blackader, who is one of the Charter Members of the Club and a Past President. The painting is in the best style of the artist, M. Jongers, and depicts Dr Blackader in his scarlet robes as a Doctor of Laws of McGill University.

Dr H S Birkett, whose remarks were very happy, spoke as follows:

"The duty allotted to me this evening is a great privilege and pleasure, the latter however being considerably marred by the absence through illness of our honoured friend Dr Blackader. We all much regret his absence and are glad to learn that he is making satisfactory progress.

"There are but two or three of us here present this evening whose privilege it has been to have been companions in his professional journey for part of the time, and I think that we have been able to watch his career with added interest. Our first acquaintance with Dr Blackader was in the Out Patient Department of the Montreal General Hospital. Here he was to go forward, putting into practice the work of his specialty, the foundations of which had been laid by extensive study in the hospitals of Great Britain and Europe, and in his clinics one saw his application of the humanities, in the care and consideration for his patients in all walks of life. The poor received the same kindly and courtly attention that he gave the rich. In this department of the Montreal General Hospital his knowledge was broadened and deepened and led to the production of scientific and literary work of such a high character that he became recognized as a great leader in his specialty and his efforts were recognized by leading Societies in Great Britain and the United States conferring distinction and honours upon him. These attainments were also recognized in his own country and by his Alma Mater, the latter conferring upon him the honorary degree of LL.D. Thus, each milestone of his professional life has been marked by a distinct incident and now the members of the Club have also recognized his service to it as an original member and Past President by having his portrait painted by a very distinguished artist, M. Jongers, which acquisition will long serve to remind us of a kind and courtly gentleman and a beloved physician."

GEORGE HALL

Professor W W Chipman of McGill University, was granted the degree of Doctor of Laws honoris

causa, at the recent convocation of Dalhousie University

Promotions in the Faculty of Medicine at McGill University include the following Dr F H Mackay, from lecturer to clinical professor of neurology, Dr J A Nutter, from lecturer to clinical professor of orthopaedic surgery, Dr H M Little, from assistant professor to clinical professor of obstetrics and gynaecology, Dr J R Fraser, from lecturer to clinical professor of obstetrics and gynaecology, Dr H G Burgess, from lecturer to professor of gynaecology and obstetrics, Dr J R Goodall, from lecturer to clinical professor of obstetrics and gynaecology, Dr J W Duncan, from lecturer to clinical professor of obstetrics and gynaecology, Dr E Hamilton White, from demonstrator to lecturer in otolaryngology, Dr A W Young, from demonstrator in neuropathology to lecturer in neurology, Dr W J Patterson, from demonstrator to lecturer in orthopaedic surgery

Dr J A Wright has been appointed Research Fellow in Pathology in the Faculty of Medicine, and

Dr P J Kearns, Clara Law Fellow in Obstetrics and Gynaecology

Drs R R Fitzgerald, Dudley E Ross, H M Elder, and P G Silver, have been appointed demonstrators in anatomy, while Dr G G Miller, has been appointed an assistant demonstrator in surgery. These appointed to be assistant demonstrators in pathology are Drs Neil McLeod, John E deBelle, A W Blair, George D L Taylor, P N MacDermot, and G N Paterson Smyth

Major James Stevenson has been promoted to the rank of lieutenant colonel and placed in command of No 6 Stationary Hospital, C.A.M.C., Quebec. During the war, he was officer in charge of the Quebec Military Hospital

Captain A E Lundon has been promoted to the command of No 6 Field Ambulance, C.A.M.C., in succession to Colonel S H McKee, CMG, who is appointed to the command of No 6 Reserve Field Ambulance

ONTARIO

The opening meeting of the Academy of Medicine, Toronto, took place on Tuesday, October 2nd. According to the general custom this, the president's meeting, was preceded by the annual dinner, a dinner at which more than two hundred of the Fellows were present. There were many guests, including Sir Samuel Squero Sprigge, the Editor of *The Lancet*, Mr Keyne of Barts, Dr Hugh Thursfield, Sir Robert Falconer, and the chairman of the various hospital boards, all of whom contributed to the dinner by their timely remarks, remarks which dealt largely with the problems of post graduate education in London. Towards the end of the dinner the many friends of Dr Marlew, the President, were delighted to see him appear after his long illness and absence, and were especially pleased that he was able to make a few remarks before leaving. Dr W Warner Jones, Vice president, acted as chairman at the dinner, and presided at the stated meeting, later. After the introductory remarks by the Vice president, Dr H B Anderson, Chairman of the Board of Trustees presented a report which outlined the future policy of the Academy. In this report the Fellows were reminded that the question of a new building would have to be met in the very near future. Details of finance and of building plans were brought forward, and, as the report indicated, it is quite evident that the greatest of the forward steps of this progressive institution is in process of being made. Drs Andrew Eadie, George H Bewles, and George Balmer were elected to Life Fellowship. The election of the representatives of the Academy upon the Committee on General Purposes of the Ontario Medical Association took place. The address of the evening was given by Dr Hugh Thursfield, St Bartholemew's Hospital, London, England, who took as his subject, "The thymus gland and so called thymic asthma."

The Section of Medicine met on Tuesday, October 9th. After the chairman's address, the following papers were presented "Relation of the altitude of the sun to its antirachitic effect," by Drs F F Tisdale, and Alan Brown, "Cases of subacute bacterial endocarditis," by Dr Harris McPhedran

District Number Five of the Ontario Medical Association met in Barrie, October 3, 1928. The following program comprised the day's meeting "Factors contributing towards reduction of surgical

failures," by Dr J K. McGregor, Hamilton, "A review of the Medical and Narcotic Drug Acts, with some difficulties arising out of their attempted enforcement," by Dr E A McQuade, Trenton, President of the Ontario Medical Association, "Hypertension," by Dr Geo S Young, Toronto, "Some aspects of the prostatic problem," (lantern slides), by Dr F S Patch, Montreal.

Addresses were also given by Dr R T Noble, representing the College of Physicians and Surgeons of Ontario, and Dr T C Routley, Secretary of the Ontario Medical Association

A short business session was held at which Dr W A Lewis of Barrie was nominated Counsellor of the District for the ensuing year, and Dr S W Otten of Newmarket was elected Vice counsellor. Considerable interest was displayed in the problem of the drug addict, and a resolution was passed with the unanimous approval of the meeting, memorializing the provincial government to provide adequate hospital accommodation for drug addicts, and also to make provision for their committal thereto

It was the unanimous opinion of all these present that this meeting was a decided success and one of the best ever held in the District

Little by little the general plan of the new St Michael's Hospital is taking form, and this splendid institution, the equal of any of its size in Canada, is appearing as a compact new building able to accommodate six hundred patients. The latest addition, a seven story building, is fireproof, and with its light halls, bright wards, well equipped diet kitchen is unsurpassed. It is a remarkable addition to Toronto's hospital accommodation. There are no fewer than seventy-five private rooms, and almost an equal number of semi-private, and in connection with them there are eight operating rooms, together with a new emergency ward and its equipment. The broad minded attitude of the trustees and managers is seen in the generous provision for laboratories, a whole floor is given over to the x-ray department, and another floor is provided for the clinical laboratories, which to an observing eye seem as complete in their equipment and as extensive in their space as any of the best on the continent. When one adds to this detail the fact that these laboratories are under the supervision of a

pathologist such as Dr Magner, one realizes that St Michael's is determined to maintain its high standard of efficiency. With its equipment, with its professional staff, and with its capable and managing sisterhood, St. Michael's in its new surrounding stands far forward in the ranks of Canadian Hospitals. N B GWYN

The Ontario Neuro Psychiatric Association will meet at the Psychiatric Hospital, Toronto, on November 16th. A business meeting will be held from 5 to 6 o'clock and papers, clinical demonstrations and discussions will begin at 8:30 p.m. G C KROD,
Secretary

MANITOBA

The epidemic of poliomyelitis, which began in Winnipeg in July, reached its peak in August and spread to other points in Manitoba, but by the end of the first week in October it had subsided, and it is expected that few if any further cases will be reported for the balance of the year. Up to October 17th, 395 cases were reported, 250 from Winnipeg and 145 from other Manitoba points, with a total of 28 deaths. The Winnipeg schools which were to have opened on September 4th did not open until October 1st. Convalescent serum was used extensively, with excellent results if given before the onset of paralytic symptoms. Great praise must be given to the Medical Research Committee, which directed the collection and distribution of serum, and to the Winnipeg Medical Society, which was responsible for calling an emergency meeting of the profession and appointing a committee that prepared valuable articles on the diagnosis and treatment of the disease for the public press. The work of these two bodies created a certain feeling of security in the minds of the lay public and prevented any panic. The Medical Research Committee is now engaged in preparing a report on this epidemic and the effect of convalescent serum therapy and this report when presented will undoubtedly be of considerable value. By months the number of cases reported and the deaths are as follows—

	Winnipeg		Rural and Suburban Manitoba	
	Cases	Deaths	Cases	Deaths
July	9	3	1	0
August	79	9	21	4
September	154	7	111	5
Oct 16	8	0	12	0
(inclusive)	—	—	—	—
Total	250	19	145	9

It should be borne in mind in connection with the deaths assigned to Winnipeg that these may include non residents of the city who were brought to city hospitals for treatment.

The contract for the building of the first wing of the Deer Lodge Military Hospital, on the outskirts of Winnipeg, was awarded on September 21st, the estimated cost being \$131,571. The wing will be built on the east side of the present building and will provide wards for bed patients. It will be three storeys in height and will have a recreation floor on the roof.

On October 2nd, at the Metropolitan Theatre, Winnipeg, and under the auspices of the Winnipeg Medical Society, Dr James Miller, Director of the Richardson Laboratories, Queen's University, Kingston, showed the

The department of Anatomy of the University of Western Ontario, London, has been re organized by its Professor and Chief, C C Macklin, FRSC. Dr H Alan Skinner, M.B. (Tor), has been appointed Assistant Professor of Anatomy, and E N Ballantyne, B.A., M.D., M.Sc., Carl G Smith, B.A., and W K Welsh, M.B. (Tor), are full time instructors. The part time instructors are H M Simpson, M.D., M.Sc., FRCS (Edin), Hermann E Schaef, M.D., Leonard W Pritchett, M.D., R A Johnston, M.D., H O Foucar, B.A., M.D., and Madgo Thurlow Macklin, A.B., M.D. (Johns Hopkins). Messrs Calder, Gilchrist and Rogers are student assistants.

intensely interesting Canti film. This film which has been presented by Dr R G Canti to the Canadian Medical Association, depicts normal cell reproduction and the effects of radium on cancer cells. A large audience was present.

At the regular monthly meeting of the Winnipeg Medical Society, held on September 21st, Dr N J Maclean presented a paper on "Tumours of the upper left abdomen," Dr Geo V Bedford spoke on "Thallium therapy in ringworm of the scalp," while Dr M J Ormerod discussed "The pharmacology of thallium." Dr A. W. S. Hay was elected to membership.

The seventeenth annual meeting of the Canadian Public Health Association was held in the Royal Alexandra Hotel, Winnipeg, on October 11th, 12th, 13th, with Dr Geo D Porter, of Toronto, presiding.

The Winnipeg Health League, under the able leadership of Dr H M Speechly, has prepared an imposing list of speakers to address audiences during the coming winter and spring. The subjects to be presented cover a wide field and fall into three groups: (a) to parents and adults interested in child training, (b) to general audiences, and (c) to adolescents. The addresses will be given not only at meetings directly under the auspices of the Winnipeg Health League but to service clubs, women's organizations, and others, and in addition radio talks of one half hour duration will be given.

In the Manitoba University Alumni Golf Tournament, held at Southwood on October 5th, Dr W D Mann won the men's low gross score. The low net ended in a tie between Dr G S Fahrni and W A Lendal of Law. Medicals won the inter faculty team match. The ladies low gross score was won by Mrs (Dr) G B McTavish.

Dr C W Duncan has opened an office in Winnipeg.

The contract for the building of Mount Carmel Clinic at Austin Street and Sellars Avenue, Winnipeg, has been awarded. ROSS MITCHELL

At the last meeting of the Executive of the Manitoba Medical Association, the following were appointed to the Editorial Board of the *Canadian Medical Association Journal*, as representing Manitoba: Dr Ross Mitchell, (Chairman), Dr H M Speechly, (Secretary), Dr C R Gilmour, Dr L D Collin, Dr J D McEachern.

SASKATCHEWAN

Dr R O Davison, Director, Division of Communicable Disease, Department of Public Health, Saskatchewan, addressed the regular monthly meeting of the Regina and District Medical Society, September 5th, on "Immunization and serum treatment." This interesting and instructive paper provoked much discussion.

Dr M M Seymour then addressed the meeting on "Health districts in Saskatchewan." A summary of this is found elsewhere in this *Journal* (p 598). The meeting expressed its appreciation of the work done in the province in disease prevention by the department and hoped to co operate in this work.

Dr W A Dakin was elected a delegate to the annual meeting at Prince Albert. Dr H H Mitchell was appointed representative to the executive of the Saskatchewan Medical Association for the coming year.

The Society recommended to the Junior Red Cross committee that a doctor be appointed as house physician to the Junior Red Cross Hospital.

The epidemic of poliomyelitis in Manitoba was discussed with a view to preparedness in case the disease spread to the Regina district. The meeting passed a resolution requesting the Department of Public Health to get the consent of patients or of the parents of junior patients who have had poliomyelitis to collect blood for the purpose of manufacturing convalescent serum if it is found necessary.

Dr Harvey Agnew, Associate Secretary of the Canadian Medical Association and Secretary of the Department of Hospital Service, addressed the Annual Meeting of the Regina and District Medical Society, which was held on October 4th.

Dr Henry gave a short résumé of his trip to Europe, where he visited the different men engaged in x-ray and therapy work in the various centres, London, Manchester, Edinburgh, Paris, Munich, Vienna and Berlin, and attended the Second International Radiological Congress in Stockholm.

Among the interesting work seen was that of Dr Beclère, of Paris, who kindly demonstrated intra uterine technique, with the use of hypodermic pressure, and illustrated his cases with lantern slides.

A very interesting and instructive week was spent at Vienna, under the supervision of Dr Schuller. At the Convention at Stockholm a few of the many interesting cases were mentioned, special stress being placed upon the papers which gave a description of treatment of psoriasis, and also the treatment of asthma by x-rays.

Before proceeding to the business meeting the members rose and observed a moment's silence in honour of the late Dr F J Ball who had been a former president of the society.

Dr B C Leech was appointed house physician to the Junior Red Cross Hospital, Regina.

The matter of a Victorian Order nurse for Regina was discussed briefly and left for the incoming officers to deal with.

Dr S E Moore, Treasurer, gave his report, which was accepted. The election of officers resulted as follows:

Hon President, Dr M M Seymour, President, Dr R O Davison, First Vice president, Dr W A Dakin, Second Vice president, Dr R R Roger, Secretary, Dr P L Straith, Treasurer, Dr S E Moore, Executive, Drs J C Black, J B Ritchie, S Kraminsky, W A Harvey, and G H Sahlmark.

The President, Dr H H Mitchell, gave a short review of the very satisfactory year's work. There were ten regular meetings and three meetings visited by

post graduate teams. He thanked the members for their active and harmonious support.

P L STRAITH

The third annual convention of the Saskatchewan Health Officials' Association was held at Saskatoon on October 9th at the King George Hotel.

After the President's address, by Dr H C Burroughs, of Swift Current, the following scientific papers were given: "Restricted areas for tuberculin testing, and their relation to public health," by Dr C J Johannes, Veterinary Inspector, Health of Animals Branch, Dominion Government, "Inspection of food places," by Mr H G Buck, Food Inspector, City Health Department, Saskatoon, "How foods are tampered with," by Mr E G Southou, Sanitary Officer, Swift Current.

In the afternoon the following papers were read: "The relation of the sun to general health," by Dr John Orr, Saskatchewan Anti-Tuberculosis League, "Public health nursing," by Miss Ruby Simpson, R N, Assistant Director, Division of Public Health Nursing, Department of Health, Saskatchewan, "Communicable diseases," by Dr R O Davison, Director, Division of Communicable Diseases, Department of Public Health, Saskatchewan, "Problems of the rural health officer," by Dr A O Rose, M H O, Hafford, "Some of the difficulties of the part time health officer," by Dr J H H Jackson, M H O, North Battleford, "The city medical health officer," by Dr W R Coles, Regina.

The round table discussion at 4:30 p.m. was led by Dr Arthur Wilson, M H O, Saskatoon.

After dinner addresses were given by Hon J M Ulrich, M.D., Minister of Public Health, by Dr M M Seymour, former Deputy Minister of Health, now Special Adviser on Public Health to the Saskatchewan Government, and by Dr MacLeod Harris, Chief of Laboratory and Hygiene, Department of Pensions and National Health, Ottawa.

At the business meeting which was held in the evening the officers for next year were elected as follows: Patrons, His Hon Lieut Governor H W Newlands, Hon J G Gardner, Premier, Hon J M Ulrich, Honorary President, M M Seymour, M.D., D P H, President, J H H Jackson, M.D., M H O, North Battleford, Vice President, W R Coles, M.D., M H O, Regina, Executive Ruby M Simpson, Regina, Paul McElmorie, Regina, W H Orme, M.D., Saskatoon, D R Davies, M.D., MOIL, Estevan, B M Bayley, M.D., M H O, Moose Jaw, R G Ferguson, M.D., Fort Qu'Appelle Sanatorium, H C Burroughs, M.D., M H O, Swift Current.

Speakers from Saskatchewan at the Canadian Public Health Association Convention held at Winnipeg, on October 11th, 12th and 13th, were Dr Arthur Wilson, M H O, Saskatoon, on "The authority of the medical officer of health in his own community," R H Murray, Director, Division of Sanitation, Department of Public Health, Saskatchewan, on "The Control of public milk supplies," Dr F C Middleton, Acting Deputy Minister of Health, Saskatchewan, on "The movement toward full time Health units in Saskatchewan" and "The periodic examination as a public health measure," Miss Marion Landeburgh, R N, on "Health teaching in high schools."

The following Saskatchewan representatives were elected on the Executive Council: Dr Arthur Wilson, Saskatoon, Dr J H H Jackson, North Battleford, Dr F C Middleton, Regina.

Dr H H Hepburn, F.R.C.S., of Edmonton, and Dr W H Merritt, of Calgary, toured Saskatchewan in October giving post graduate lectures to the local societies. They were guests of the Regina General Hospital at lunch on October 19th, at which time they spoke on "Encephalitis" and "The surgical treatment of neuritis." At the evening meeting, after a dinner at the Hotel Saskatchewan, Dr Hepburn spoke on "Treatment of head injuries," and Dr Merritt spoke on "Peptic ulcer." They were accompanied by Dr A MacG Young, Secretary of the Saskatchewan Medical Association.

The School Hygiene Branch of the Department of Education was organized in April, 1917, with a staff which has gradually increased to fourteen nurses. All of the 4,770 organized districts have been visited by

school nurses, some of them have been visited four or five times. Correction of the remediable defects by the family physician has been vigorously sought. The teaching of health in the schools has been carried on. Saskatchewan was the first province in Canada to introduce health education in the Normal Schools, directed by public health nurses with teaching backgrounds.

On May 1, 1928, the School Hygiene Branch of the Department of Education was transferred to the Department of Public Health, and, associated with the nurses who are already in the Department of Public Health, will in future be known as the Division of Public Health Nursing. The object of merging the two branches was to unify the service and avoid duplication of effort. A plan of generalized public health work has been arranged with special districts allotted to each of the sixteen nurses now in the field.

ALBERTA

The September meeting of the Academy of Medicine, following the summer vacation, was held at the summer residence of the President, Dr J F Folinsbee seven miles from Edmonton centre, overlooking the Saskatchewan River. Some sixty of the members of the Academy were present and a discussion took place in reference to (1) the report of the committee on the proposed Medical Arts building in the city, similar to that already established in the city of Winnipeg, (2) the disposition of the library of the Academy of Medicine, the final decision here being made to make a gift of it to the Medical Library of the University of Alberta, the books to be available for the use of all medical men of Alberta. Following the meeting a very enjoyable buffet luncheon was served in the billiard room, a most enjoyable time being spent partaking of the hospitality of our genial President.

Dr G E Swallow has recently been appointed Assistant Medical Inspector of Schools, on part time, by the Edmonton School Board. T H. WHITELAW

In the new form of Application for Registration in Alberta, provision is made for a certificate of character from registrars in other districts where the applicant has practised. The idea is that Alberta is no longer the "wild and woolly west" to which a man may go after conducting himself in a manner unworthy of his profession, and expect to be received with open arms. Alberta intends that future registrants who are "wanderers" shall show good reasons for their acceptance.

The following have just registered in Alberta: Dr Robert Fraser Stewart, Coleman; Dr Arthur Wychiffe Scott, Calgary; Dr Harold Warnica Price, Calgary; Dr Elgar Emrys Evans, Calgary.

Through the courtesy of the Canadian Medical Association Dr Canti's film, "Growth of Tumour Cells in Vitro" was exhibited in the Palace Theatre, Calgary, by Prof James Miller of Queen's University, Kingston. In addition to the local medical men, the following were invited to view the film, newspaper

editors, dentists, druggists, the legal profession, the Ministerial Association, school teachers, and nurses. The theatre was well filled and general delight and approval was manifested by all.

Calgary regrets exceedingly that one of the "real old timers" in the practice of medicine should have been transferred to Vancouver, in the person of Dr R D Sanson, and the fact that his new appointment is a promotion only lightly affects the general feeling of regret.

Dr E A Johnson, a recent graduate of Alberta University, has purchased the practice of Dr De Beaupré, of Fort Saskatchewan, and is already at work.

Dr Edward G Hollics, of Edmonton, has taken over the practice of Dr Huckell at Waskatenau, the latter going to the University Hospital as assistant to Dr Mewburn in orthopaedic surgery.

Dr H C Swartzlander has disposed of his practice in Oyen and is moving to Calgary. Dr S R McGregor, formerly of Red Deer, is succeeding him.

Dr W W Nasmith, of Sylvan Lake, suffered a severe loss in the death of his wife recently, and his many friends extend their heartfelt sympathy to him at this time.

Dr James Kennv, of Retlaw has just returned from a three months' internship in Buffalo Hospital, and is intending to remain in Alberta.

Dr George R Johnson, Registrar, has gone to Halifax to attend the 75th Anniversary of the Nova Scotia Medical Association. He will give a lecture on early medicine in Alberta. On his way to Halifax he will do some post graduate work.

Dr Katherine M Hick, M.R.C.S. Eng., has accepted an appointment in the Municipal Hospital, Onoway, Alta. W G HUTT

BRITISH COLUMBIA

The winter session of the Vancouver Medical Association was opened on Tuesday, October 2nd, with papers by Dr J J Mason on "Genital prolapse," and "The technique of version" by Dr W B Burnett. The first of the season's business meetings was held prior to the scientific papers. The report of the Summer School, held in June, 1928, was given by the Chairman, Dr H R Stoors, who reported a substantial balance to the credit of the School in the funds of the Association. Dr Wilfrid L Graham and Dr R P Kinsman were elected to serve on the committee of the Summer School for the next three years. Assistance has been rendered to the committee during the past three years by the Canadian Medical Association in supplying some of the speakers. For 1929 it is possible the committee may adopt a different policy, with regard to obtaining speakers in other ways. Eight new members were elected by the Association, Drs A M Agnew, E E Day, W L Graham, W H Hatfield, C T McCallum, D M Meekison, H R Mustard, and J Eden Walker, bringing up the total membership to 221.

Several of the younger members of the Association have recently formed a reading society under the proposed title of "The Osler Society of Vancouver." Meetings will be held monthly, and at each meeting two papers will be given, the discussion on which will be led by one of the older members of the Association who will be invited to attend the meeting. It is hoped that free discussion will lead to full attendance at each meeting.

It is anticipated that the new Private Ward Wing of the Vancouver General Hospital will be opened in the near future. Furnishing is now under way and the new beds will probably be ready for occupation earlier than was anticipated. The new maternity wing is also nearing completion.

In view of the pending amalgamation of the adjoining municipalities with Vancouver, and the consequent changes that will be necessary in the Health Department, the Vancouver Medical Association, on a motion by Dr A S Monro, recently appointed a committee to make a public health survey of the proposed greater city of Vancouver. The committee is busy investigating and a full report is promised for the November meeting of the Association.

The fourth extra mural post graduate tour through out British Columbia has just been completed and it will be interesting to the Canadian Medical Association and the Sun Life Assurance Company to know that it was an unqualified success. Lectures were given at Cranbrook, Grand Forks, Kelowna, Vancouver, Chilliwack, Nanaimo, Victoria, Prince Rupert and Prince George. Outside the larger centres of Vancouver and Victoria tremendous mileage was covered by the doctors in their anxiety to attend the meetings, and this, plus the enthusiasm and the keen appreciation of the addresses must have been gratifying to the distinguished speakers selected for us.

It was indeed an honour to have Dr A T Bazin and Dr A H Gordon, of McGill University, and Dr Gordon Bates, of Toronto, with us. Dr Theo H Lennie, Vice-President of the British Columbia Medical Association and Dr Howard Spohn accompanied the speakers on their tour. The annual meetings of the East Kootenay, West Kootenay and Okanagan Medical Societies were held concurrently with the

post graduate meetings. Dr F W Green, of Cranbrook, was elected President of the East Kootenay Society, Dr H H McKenzie, of Nelson, President of the West Kootenay, and Dr A L Jones, of Revelstoke, President of the Okanagan Medical Society.

Dr W L Graham and C H Bastin have been appointed the representatives for British Columbia on the Editorial Board of the Canadian Medical Association.

We welcome home our Executive Secretary, Mr C J Fletcher, who has just returned from the Mayo Clinic and hope he will soon be his genial self once more.

Dr W E Tiffin of Kimberley has taken over the practice of Dr D Wannop, Nanton, Alberta.

Dr J A Ireland has been appointed Medical Officer at Atlin, B C.

Dr C R Marlatt has resigned the position of Medical Superintendent of the Powell River Sick Benefit Society, effective on December 1st. Dr Marlatt, who has been practising in Powell River for the last nine years, will continue there in private practice. Dr A S Underhill is acting as his assistant.

Dr J A Stewart, eye, ear, nose and throat specialist, of Victoria, is now en route to Vienna, where he will do post graduate study in his specialty.

Dr F M Bryant of Victoria is now back in practice, following a successful operation.

Dr E M Casey of Montreal and Dr J R Langley of Harvard are now at the Royal Jubilee Hospital, Victoria, as internes.

The Victoria Medical Society held a dinner on September 7th, when Dr A T Bazin and Dr A H Gordon of Montreal, and Dr Gordon Bates of Toronto were the guests of honour, and addressed the members. Dr Bazin dealt with "Some diseases of the gall bladder" and Dr Gordon read a paper on "Nephritis" following which Dr Bates addressed the society dealing with the control of venereal disease when he was able to show convincingly the magnitude of the problem confronting the profession. On September 8th, Dr Bazin addressed the members after luncheon at the Union Club his subject being "Varicose veins." In the evening Dr Gordon read a paper on "Digitalis therapy" and Dr Bazin dealt with "Inguinal hernia." Dr Gordon Bates showed some very interesting lantern slides. At the close of this evening a vote of thanks was passed to the three visiting speakers on motion of Dr George Hall. The Society was very fortunate in having two days so pregnant with instruction and was especially grateful to Dr Gordon Bates for giving two public lectures on "Preventive medicine." These lectures were well attended. The arrangements were carried out by Dr M G Thomson who is now in British Columbia organizing and carrying on the program of the National Social Hygiene Council.

Since undertaking the production of Monoaceticacidester of Salicylic Acid in 1914, consistent research and development carried on in the Frosst laboratory has resulted in a large and varied list of Acetophen combinations

Most of the formulæ listed in the column on the left, originated in the Frosst laboratory and have been given wide recognition by the medical profession from Coast to Coast. New combinations have been consistently added, among which the assortment of Acetophen tablets of appropriate strength for children deserves special mention. Being sweetened, they are very acceptable to the child.

The Frosst label on tablets is an assurance of high quality of ingredients, rapid disintegration and accuracy of dosage and we believe that the accompanying list indicates the extent to which the Frosst laboratory is employing its technical resources to assist the physician.

Many of the tablets listed here are obtainable in several colors in addition to white.

UNITED STATES

A Gift for Radium

A gift of \$100,000, from Col Louis J Kolb, of Germantown, has been received by the Graduate Hospital of the University of Pennsylvania and the Department of Radiology of the University's Graduate School of Medicine. It is intended for the purchase of a gram of radium and the accessories for use in the treatment of cancer. About \$72,000 will be required for the purchase of the radium, and the balance will be applied to the expenses involved in the special chemical and medical work. Col Kolb's gift is the second to be received by the University within the last ten months for the control of cancer, Mr. I DuPont having donated \$45,000 last December. As a result of Mr DuPont's gift a study of the physico-chemical conditions associated with the cancer state is being made, under the direction of a committee consisting of Drs Ellice McDonald, W C Sefriz, and Dean Meeker.

Sir Robert Philip

Sir Robert Philip, of Edinburgh, who established the first Tuberculosis Dispensary in 1887, and developed the Edinburgh System of Tuberculosis Control, was awarded the Trudeau Medal at the recent annual meeting of the National Tuberculosis Association. Sir Robert is the first foreign physician to be so honoured.

National Tuberculosis Association

At the annual meeting of the National Tuberculosis Association, held recently in Portland, Ore, Dr Eugene L Opie, of the Henry Phipps Institute, Philadelphia, was elected President, and Dr Ray W Matson, of Portland, Vice President.

New York Academy of Medicine

The Bulletin of the New York Academy of Medicine for August contains the list of the recent Harvey Exhibit, planned and arranged by Dr Archibald Malloch, Labraman, and shown in the library of the Academy.

GENERAL

Medical Council of Canada

At the recent examinations of the Council, held in Montreal and Winnipeg, the following candidates were successful: A Aubry, Lancaster, Ont, C G Bain, Tofield, Alta, M M Band, Fredericton, N B, D M Baltzan, Brooklyn, N Y, A W Blair, Regina, F W Boyd, Winnipeg, J L Brown, Regina, R F Brown, Toronto, J B Cramer, Westbrook, Ont, P E Doyle, Hawkesbury, Ont, J R Forrest, Montreal, R Gottheb, Vienna, Austria, N L Higginbotham, Lethbridge, Alta, L Jordan, Winnipeg, R H Kinsman, Toronto, S W Leske, Seattle, Wash, K. M Lind say, London, Ont, Muriel MacLennan, Westmount, H McKenzie, Dungannon, Ont, E M McLean, Port of Spain, Trinidad, R B Michener, Wichita, Kan, J Mindess, Winnipeg, J A Murison, Kindersley, Sask, F J Murphy, Red Deer, Alta., E B Potts, St Thomas, Ont, E Poutontaine, St Pierre, Man, E L Reid, Scotland, A Scharf, Moose Jaw, L Sinotte, Ottawa, D Stredig, Flora, Ont, J B Thompson, Orono, Ont, J G Toombs, Mt Stewart, P. E. I., W M Wallace, Toronto, J F Whitworth, Vancouver, J W Walton, Ayr, Ont.

These physicians are now registered as of date October 12, 1928.

Professor v Muller

The seventieth birthday of Geheimrath Prof Friedrich v Muller, of Munich, who, it will be remembered, visited Canada some twenty years ago and lectured in various cities, was celebrated on September 19th. The auditorium of the Second Medical Clinic in Munich was too small to accommodate the crowds of his former students and his friends who flocked there. Professor Martini spoke on behalf of the students words of admiration and affection, and presented a bronze bust by Weckbecker, subscribed for by the students. Professor Staehelin, of Basel, spoke for the old pupils and the Medical Faculty of Basel, presenting Prof v Muller with a beautiful casket containing photographs of former students and friends. The Minister of Education, Herr Goldenberger, represented the Bavarian Government and Dr Schupfer, the Rector, spoke for the University of Munich.

Prof v Muller thanked the various speakers feelingly and in appropriate terms. His word to the physicians was—to keep themselves always free and independent.

Book Reviews

Diseases of the Gall Bladder and Bile Ducts, Evarts Ambrose Graham, A B, M D, Warren Henry Cole, B S, M D, and others. 477 pages, 224 illustrations. Price \$5.00 net. Lea & Febiger, Philadelphia, 1928.

The main reasons given in the preface for the publication of this book are "the growing realization of the frequency and of the importance of diseases of the biliary system" and the fact that "no comprehensive discussion of this subject has appeared in the English language since Rolleston's classical work was published in 1905."

Both of these are thoroughly sound but the authors rather lay themselves open to criticism for gross exaggeration when they state that "approxim-

ately 40 per cent of our adult population have disorders of their biliary systems." If all other causes of ill health were added to this high percentage, it is amazing how the work of the world can be carried on as it is. Possibly the enthusiast in his subject may be excused to a degree for being carried away in this way, as well as for the prominence which is given throughout the book to cholecystography, for the discovery of which the author is responsible.

In a general way, the objective of giving a systematic outline of biliary diseases has been very successfully accomplished. The complete review of the recent advances and researches fills a much needed place in the book literature on this subject, about one third of the book being devoted to experimental

An ECHO of

THE CANADIAN MEDICAL ASSOCIATION JOURNAL

and clinical cholecystography and to the discussion of the various tests of hepatic function

In discussing the anatomy of the biliary system, the importance of the lymphatics is fully described and excellent plates show the variations in the arteries and ducts of the biliary tract. The authors have succeeded in presenting a fair evaluation of the present knowledge of the functions of the gall bladder, but no mention is made of the normal relation of the flow of the bile into the duodenum in its relationship to the cycle of digestion, overlooking the fact that the biliary is an accessory part of the alimentary system.

The chapters on symptoms and clinical diagnosis are entirely inadequate in a work that professes to cover this whole subject. The practitioner will gain little help in the diagnosis of disorders of the biliary tract, as the descriptions of their characteristic features. Resort is made to quoting statistical frequency of certain types of cases that occur receives little attention. One is almost forced to the opinion that the bedside study of cases has failed to interest the authors to the same degree as the laboratory research work and the literature. The discussion of visceroptosis, spasms, constipation, and intestinal allergy, but as duodenal and gastric ulcer and carcinoma, and lesions of the appendix and kidney. The clinical differences in the pathological processes that simulate chronic cholecystitis and cholelithiasis have failed to find a place.

The surgical treatment is well described and illustrated, but the practitioner receives but few suggestions in the methods of handling cases before they reach the stage when operation is clearly indicated.

The book is well published and the illustrations are well reproduced. More pictures of pathological gall bladders and the types of gall stones, with fewer of laboratory tests, would have filled a much needed want. The book as a whole will prove an exceedingly useful one for both the student and practitioner, more especially from the point of view of the recent experimental investigations that have been conducted. It will help to fill the gap between 1905 and the present, but still leaves room for an author of wide clinical and pathological experience and an appreciation of research, to write an evenly balanced monograph on this increasingly popular subject.

E G RYERSON

Epilepsy Medicine Monograph No XIV William G Lennox and Stanley Cobb 197 pages, illustrated Price \$3.50 Williams & Wilkins Co, Baltimore, 1928

The scope of the book has been carefully confined to "the presentation of evidence which may throw light on the mechanism involved in seizures and on the cause and treatment."

The authors first give briefly and clearly the different theories commonly held as to the neurological mechanisms of convulsions. The next and major portion of the work is devoted to a consideration of the different factors which may or may not cause convulsions. The last section contains a short review of modern methods of treatment. These three aspects condensed, but adequately discussed, within the compass of some one hundred and fifty pages. The authors have evidently reviewed the existing literature very exhaustively and have presented the evidence for varying views and theories, including their own, con-

servatively and impartially. The very large and complete bibliography attached to the work allows the reader to take advantage of what has quite evidently been a very careful and laborious search of the literature. Each section is closed with a short summary of the matters discussed therein and this together with the fact that the book is written in clear concise English enables one to read it in one evening without that sonso of fatigue that is so often experienced when perusing medical literature.

E C MENZIES

New and Nonofficial Remedies, 1928. Published by the American Medical Association, Chicago Price \$1.50

No official pharmacopœia can be expected to deal with all the additional remedies which are continually appearing. And yet it is well known that many of those remedies are of great value. It is also well known however that many remedies that are offered for sale have little or no value. It is to fill the gap in the official viewpoint regarding these two classes of remedies that the Council of Pharmacy and Chemistry of the American Medical Association publish each year a volume which lists and describes the articles accepted by them as worthy of recognition. There is an illuminating section devoted to "articles described" but not accepted.

The book is valuable also in its revision and bringing up to date our knowledge on substances in common use such as arsenic compounds, barbitals, digestive enzymes, iron and iron compounds, scrums and vaccines, glandular preparations, etc. It has also been necessary to add new material in the articles on medicinal foods and ergot preparations.

The book is extremely useful and contains information which the general practitioner will frequently require and which he can obtain nowhere else.

H E MACDERMOT

Preventive Medicine Mark F Boyd, M.D., M.S., C.P.H., Member of Regular Field Staff, International Health Division of the Rockefeller Foundation Third edition, revised, 475 pages Illustrated, \$4.50 London and Philadelphia, W B Saunders Company, Toronto, McAllister & Co, 1928

That a volume such as this should have reached a third edition, in which all recent advances are recorded, is most satisfactory indeed, for it proves that the medical profession is taking a deeper interest in public health than ever before. Dr Boyd has gathered together from many sources the main facts relating to preventive medicine, and has set them down concisely and clearly, so that medical men may have access to them quickly and easily. In the changing public sentiment of the past decade it is becoming very obvious that practitioners must take the lead in all fields of prevention, or it will pass into other hands.

This book is as complete as one could wish. Should one desire to follow any particular subject in more detail, there are abundant references at the end of each chapter. The illustrations, unlike those in many other text books, are original and exceedingly instructive, particularly those relating to occupational diseases and food infections. The chapters on malaria and yellow fever are worthy of mention, but the rarer infections such as undulant fever are also considered. If there is any fault to be found with the book, it is that many things are set down in table form, and give the appearance of a compendium. But in the space allotted it is not possible always to retain the narrative, and undoubtedly the tabular method of presentation makes the work more valuable for reference.

Prime Fresh Livers are Quickly Rendered for *Mead's* *Standardized Cod Liver Oil*

THE uniform potency and excellence of Mead's Standardized Cod Liver Oil, plain and flavored, is due to a number of reasons. Pre-eminently among them is the control of the cod-fisheries themselves. This is important. Next, the livers are rendered in plants in Newfoundland owned and operated by Mead Johnson and Company. This also is significant.

By control of fisheries, cod are caught in season when the livers are in prime condition for oil production. Rendering stations have been established in close proximity to the fishing waters—48 in number—so that the livers are rendered almost immediately after the fish are removed from the traps.

Washing and inspecting livers

Government Supervision

Each liver is examined by experienced inspectors—underweight and bile infected livers are thrown out. In addition to the scientific precautions taken by Mead Johnson and Company, strict supervision by the Newfoundland government is maintained over each step in the production process.

Belleville, Ontario

Lectures on Internal Medicine Knud Faber, M.D.
147 pages, 43 illustrations Price \$3 00 Paul B Hoeber, New York, 1927

The etiology and pathogenesis of achylia gastrica is the title of the Nathan Lewis Hatfield Lecture given before the College of Physicians of Philadelphia

The intestinal origin of pernicious anemia was the presentation of Faber's well known investigations in this disease to the annual meeting of the American College of Physicians at Detroit

Benign glycosæmia was the subject of the Herter Fund Lecture at Baltimore, and the Harvey Lecture at the New York Academy of Medicine was an historical outline of medical therapy

Faber's lectures on clinical subjects should be read by every physician who did not have the opportunity to hear him or who is not conversant with his views on the subjects discussed by him. The Harvey lecture, with its well chosen illustrations, is a most interesting presentation of the history of medical therapy J H ELLIOTT

Lectures on Medicine and Surgery New York Academy of Medicine First series, 1927 319 pages, 39 illustrations. Price \$5 00 Paul B Hoeber New York, 1928

The lectures appearing in this volume represent the series delivered at the New York Academy of Medicine in 1927-1927 for the general practitioner. It is a collection of general interest. Fifteen in all, they cover a wide range of subjects, cardio vascular and cutaneous syphilis, otological infections, eye conditions, general infections, contagious diseases, intestinal obstructions, surgical aspects of goitre and of medical conditions, useful drugs, the treatment of pneumonia, climate in tuberculosis, obstetrical problems, human misconduct, and the child's first year. The lectures have been given by outstanding teachers and clinicians. The book is published in Hoeber's best style, is easy to read, and can be recommended as presenting the best of recent medical thought as concerns the subjects under discussion. We think the profession in general will appreciate the work of the Academy's Committee on Medical Education

J H ELLIOTT

Collected Papers of the Mayo Clinic and Mayo Foundation. Edited by Mrs M H Mellish and H Burton Logie, M.D. 1330 pages, illustrated Price \$13 00 Philadelphia and London, W B Saunders Co, Toronto, McAlinsh & Co, 1928

This volume, as its name indicates, represents the various papers and addresses delivered by members of the Mayo Clinic and the Mayo Foundation during 1927, and published in many American and Canadian medical journals during 1927 and 1928, and here assembled in one volume. A vast amount of material is represented in this collection, however, only those which are of greatest importance, or which make most practical appeal, are here published in full, the others by title and reference only.

One cannot fail to be impressed with the vast amount of clinical material available for investigative and statistical purposes, and no less so by the research attitude which makes for such excellent work in the different departments.

No matter what the specialty, there are few pages that will not repay perusal. It would be only natural to expect, however, that one would most appreciate the sections which more directly affect his particular sphere of activity. Even allowing for this, it seems reasonable that one should single out from their excellent fellows for their particulars excellence, the papers on gastric and duodenal conditions, those on the biliary system, on renal malignancy, and suprapubic prostatectomy.

The biliary system is dealt with, from its physiological and pathological aspects, having in mind its

clinical application, and constitutes a distinct step forward in the clarification of some of its more obscure phases. The papers on cholecystography and its limitations will be found to be decidedly helpful, as setting a better standard by which to evaluate the results of the Graham test, and by virtue of the deductions made from this investigation, they who have experienced the necessity for proceeding to surgery in the presence of strongly suggestive clinical findings and negative Graham test will be confirmed in their action.

Regarding the paper on "Punch prostatectomy," we confess to a feeling of disappointment in that no very definite conclusions are given as regards the indications and contra indications of this procedure in the treatment of prostatic obstruction. The concealed knife, the cautery and the electro coagulating apparatus are all advocated, but the reader is left in doubt as to which type of instrument is preferred.

The matter is well arranged, so as to appeal to workers in all the main branches of medicine, with even some reference to dentistry, and the discussion of general subjects of the final section gives the collection a finishing touch which can scarcely be over valued. E V HOGAN

Gonococcal Urethritis in the Male for Practitioners P S Pelouze, M.D. 357 pages, illustrated Price \$5 50 London and Philadelphia, W S Saunders Co, Toronto, McAlinsh & Co, 1928

This book has been written for the purpose of conveying to the general practitioner the experiences which the author has found satisfactory in the diagnosis and treatment of acute urethritis. The first part is taken up with a study of the gonococcus, the lesions produced in the urethra and adnexa, and the modes of infection. The early and late symptoms, together with the methods of diagnosis and treatment, are taken up in detail in such a way that the reader will find a great store of small practical hints which will be very useful. The treatment outlined does not include a number of alternative treatments, to the confusion of the student, but is the one which Dr Pelouze has found of value in a large series of patients.

The chapter on the prostate includes a great many practical details of examination for diagnosis and slides of the normal and abnormal secretion. The treatment of each stage of acute and chronic urethritis is taken up in detail, together with the complications. In a special chapter devoted to non gonorrheal urethritis, stress is laid on the fact that it is more prevalent than most people realize.

The second part of the book gives an analysis of a series of patients which presented a wide range of common and uncommon complications. A critical analysis of treatment is included and should be of great value as a reference for the management of difficult cases. This monograph is a splendid effort as an outline of diagnosis and treatment of gonorrhea, by a man who has had great success with it over a period of many years. J C McCLELLAND

The Opium Problem. Charles E Terry, M.D., and Mildred Pellens. 1042 pages. Published by the Committee on Drug Addictions New York City, 1928

This volume will be invaluable to the research worker who is interested in the medico social problem of chronic opium intoxication, because the authors have made available a digest of the work that has already been done in this field. They chose the title, chronic opium intoxication, in preference to addiction, disease, appetite, habit, craving, etc, hoping that this designation would be sufficiently comprehensive to cover the different phases of the condition. The Committee on Drug Addiction has completed a biblio-

Note for the Medical Profession

A Powerful Non-Toxic Germicide

EFFECTIVE coal-tar antiseptics are severely restricted in clinical use by their damaging action on tissues. Except in a few instances, their usefulness lies mainly in the disinfection of utensils etc.

An antiseptic of equal germicidal efficiency, and without destructive action on tissues, could be employed in clinical practice for purposes and with effects hitherto unprecedented. **MONSOL IS SUCH AN ANTISEPTIC**

GERMICIDAL EFFICIENCY

Tested in the presence of organic matter, the germicidal efficiency of Monsol for faecal bacteria greatly exceeds that of other representative antiseptics. The selective action of Monsol classes it apart from any antiseptic of similar origin in that its efficiency is greatest for the Gram-positive cocci. Monsol kills the *Streptococcus Pyogenes* in a dilution *more than 10 times greater* than phenol or lysol.

TOXICITY

Monsol is absolutely non-irritant to the skin. Effective solutions of Monsol can be applied to mucous membranes. Large amounts of pure Monsol given by the alimentary tract to animals have failed to demonstrate any poisoning action. Monsol has been given intravenously to animals in amounts equivalent to no less than 1-600th of the total blood volume with only transient ill-effects. No other antiseptic exists which possesses these properties.

graphy of over six thousand items, the greater part of which is considered of little or no value (a tremendous waste of good Canadian pulpwood!) Some four hundred contributions were considered worthy of analysis.

It may surprise some to learn that De Quincey's "Confessions of an English Opium Eater" (1841), according to the authors, had far reaching effects, and even to day its pernicious effects are felt. The consensus of opinion of the writers cited is that the origin of the majority of cases of chronic opium intoxication lies in the therapeutic use of the drug, but one is cautioned to balance that against the fact that there is an incompleteness of data. Until the pathological changes have been studied and are understood no rational treatment can be applied. Some of the authors stress the difficulty of diagnosis, especially when the patient is in "perfect balance." A contracted pupil may or may not be present. No satisfactory explanation of the withdrawal symptoms has been given. There is unanimity of opinion that the manufacture of heroin should be prohibited. Nearly one-half of the volume is devoted to the study of international, national, state and municipal control. The Harrison Narcotic Law has many variations for the physicians, and if Canadian physicians wish to obviate the necessity for such a law they should become more familiar with the provisions of the Federal Opium and Narcotic Drug Act.

The index is rather meagre, but this is compensated for by the bibliography. J. W. CRANE

The Extra Pharmacopœia Vol. I. W. Harrison Martindale, Ph.D., Ph.Ch., F.C.S., and W. Wynn Westcott, M.B., D.P.H. Nineteenth edition. 1207 pages. Price 27/6 net. H. K. Lewis & Co., London, W.C.1, 1928.

A modern official pharmacopœia has at best a limited range, and there is a great necessity for something else which will include all the miscellaneous information which exists regarding drugs and their employment. The "Extra Pharmacopœia" is designed to meet this necessity. It has done so for the last forty five years, and judging by the frequent revision which it undergoes (this volume is the 19th edition) there is reason to expect that it will continue to do so for years to come.

The present edition has taken advantage of the various new editions of national pharmacopœias which have appeared in the United States, Germany, France and Sweden within the last three years. In addition to this, however, it possesses the feature which has always been outstanding in its completeness, that of abstracting the current literature over a very wide field of knowledge. It is a very unusual point on which the Extra Pharmacopœia fails to furnish some information. It is, however, on the matter of recent advances in therapeutics that one looks for guidance in new editions, and no advance of note has been omitted here. The treatment of pernicious anemia with liver, recent work on vitamin D, the use of ephedrin in asthma, recent developments in organo therapy (though still with the admission that endocrinology is far from being an exact science), discussion on lead therapy in cancer, lack of consensus of opinion on the value of tuberculin on which there is "no consensus of opinion", these are a few of the points noted.

The book is indispensable as a fully, carefully edited, and convenient index. H. E. MACDERMOT

Ernest Harold Baynes Naturalist and Crusader Raymond Gorges. 255 pages, illustrated. Price \$4.00. Houghton, Mifflin Co., Boston, 1928.

There are men whose work is not easily classified and Ernest Harold Baynes is one of them. He was a lover of animals, of flowers and wild life, and a writer of stories and a lecturer, but while he was a naturalist he had no university degrees in biology or botany, and he cannot be classed among leading modern authors.

But, he was one of those rare men whose character and charm of personality carry them through life without any of the guiding influence (sometimes cramping) of a professional training. If he was a very delightful dreamer of dreams he was also possessed of a keenly practical and well ordered mind, capable of impressing President Roosevelt to the extent of setting in motion the legislation by which the practically extinct bison was preserved and brought to the present increase of numbers, both in the United States and in Canada.

From this work he turned to the preservation of wild bird life, and this gradually absorbed his whole time. It was as a kind of climax to his years of lecturing and writing that he eventually asked a friend to write a poem for the occasion of opening a bird sanctuary at Meriden, and so occasioned the production of the masque "Sanctuary."

Shy and diffident he may have been, but he could be roused to passionate outbursts by cruelty to animals. In one of his denunciations of the trade in plumage as ornaments he said, "I do not pretend to know God, as these women who wear upon their heads the plumes of slaughtered birds claim to know Him, but if I wore such emblems of heartless vandalism on my brow, I would not have the impudence to get down on my knees and ask any favours of Him!" And again, on seeing displayed for sale one of the "Chanticleer Bow" ornaments, which had been suggested by Rostand's play, "I could hardly believe my eyes, and I looked again to make sure it was nothing less than the head of that world famous songster, the European skylark."

'Hail to thee, blythe spirit,
(Bird thou never wert),
That from heaven, or near it,
Pourest thy full heart'

Shelley's lines ran mockingly through my head, as I looked at that pathetic tiny bunch of brown feathers, with its staring glass eyes and its shrivelled bill—all that was left of the most joyous, joy giving bird that ever sprinkled the air with its songs. And the price of it, bow and all, was fifty cents! And for a tithe, then, of this paltry sum, there had been destroyed such beauty, such poetry, such joy, as could not be replaced by a syndicate of billionaires.

But even his affection for animals could not sway him into the senseless fanaticism of the anti vivisectionist. He examined the question of animal experimentation at first hand, and his investigations soon showed him what irrational and hysterical methods the anti vivisectionist worked. Far from gaining his support the anti vivisectionists found him an uncomfortably vigorous and capable opponent.

This biography manages, though with no particular literary skill, to give a picture of one with a lovable nature, a clear brain, and indomitable courage in fighting the battle of those who not only cannot fight us but should never receive anything but our admiration and affection. H. E. MACDERMOT

Sterility in Women Diagnosis and Treatment. Sidney Forsdike, M.D., B.S., F.R.C.S. 133 pages, 25 illustrations. Price 9/- net. H. K. Lewis & Co., London, 1928.

This little book might seem to be a work of supererogation in these days of so called "advanced news." But there is still some demand for the solution of this problem, and Dr. Forsdike handles the question admirably. He starts out with a definite plan of campaign, which is followed step by step to the end, unless he finds the solution sooner. And one very pleasing feature is that his plan, if he does not easily find a solution in the female side, is to shift over to the male, and make him prove his fertility, before subjecting the female to the later and more distressing parts of the examination.

The Secretary 23 ENDSLEIGH GARDENS LONDON W.C.1

The book is well written, clear, lucid and concise, and calls for nothing but praise P. M. CAMPBELL

Methods and Uses of Hypnosis and Self Hypnosis
Bernard Hollander, M.D., M.R.C.S., L.R.C.P. 191 pages Price 6/- net George Allan & Unwin Ltd, London, W.C.1, 1928

It is stated on the cover that this book will be of interest to medical and psychological experts. Most medical men and psychologists would regard the book as a popular one, and would consider the introduction of such subjects as premonitions, apparitions, clairvoyance, telepathy, the human aura and the like, as being irrelevant DAVID SLIGHT

The Examination of the Central Nervous System.
Donald Core, M.D., F.R.C.P., Honorary Assistant Physician, the Manchester Royal Infirmary, 248 pages, 14 illustrations Price \$2.75 Edinburgh, E & S Livingstone, Canada, MacMillan Co. of Canada, Toronto, 1928

To the student of medicine, to the neurologist and to others interested in the examination of the central nervous system, this will prove to be a very interesting book. As the title implies, it deals simply with the routine examination of the central nervous system and correlates some of the more common pathological signs and symptoms under the appropriate categorical syndromes.

In the main the author has not diverged from the average text book on this subject, except in the latter chapters where the nervous disorders are considered from a chronological, congenital, and mode of onset point of view A. W. YOUNG

Diseases of the Intestines Including the Liver, Gall Bladder, Pancreas and Lower Alimentary Tract.
Anthony Bassler, M.D., F.A.C.P. 905 pages, 199 illustrations Third edition Price \$10.00 F. A. Davis Co., Philadelphia, 1928

This volume is one of a series of works on present day medicine published by F. A. Davis Company. It is the third edition of this work and compares favourably with previous editions, having in addition new articles on diseases of the liver, gall bladder and pancreas. The general form of the book is pleasing, the illustrations satisfactory although the x-ray pictures could be clearer.

A considerable portion of the volume is devoted to the functions and methods of examination of the intestinal tract. Some of the examinations detailed are laborious and unnecessarily meticulous. The author appears to be favourably impressed with the Meltzer-Lyon test and has evolved some laborious tests to be done on the pancreatic juice obtained by duodenal tube. No mention is made of the starch tolerance test. Over seventy-five pages are devoted to the subjects of putrefaction, indicanuria and intestinal auto-intoxications while one or two pages suffice for Evarts Graham's work on cholecystography.

Aside from these minor discrepancies the sections on other subjects are admirably written and up to date. The section on constipation might perhaps be more emphasized, that most common of present day ailments, the spastic colon, receiving but a few lines. The book is interesting, written from the practical gastro-enterologist's standpoint rather than the academic, and will no doubt be of much value to the physician.

E. W. MONTGOMERY

A Shorter Anatomy With Practical Applications
Wolff, M.B., B.Sc., F.R.C.S. 451 pages, 130 illustrations Price 18/- net H. K. Lewis & Co., London, 1928

This book is described by the author as "A Shorter Anatomy." All well intentioned attempts to

shorten descriptions in human anatomy would be heartily welcomed by students, but one cannot quite fathom the purpose of this author in shortening anatomy by omitting such important organs as the brain, the heart, the lungs, etc. The section allotted to the thorax deals only with its surface anatomy. The author has not attempted to describe the regional anatomy of the thorax at all. It is therefore rather puzzling to determine what is the exact purpose of the book, and to which constituency it is intended to make a special appeal. If, as the author claims, "the book is especially intended for those revising their anatomy for the final examinations," how can this claim be substantiated, when the book does not cover the whole of the regional anatomy of the body?

The book is written apparently by a surgeon anatomist, which explains the fact that much space is allotted to applied anatomy. This constitutes an attractive feature of the volume. The author has attempted a semi-systematic, semi-regional plan of description. It is difficult, however, to understand why he should have decided to give an account of the courses of the nerves and blood vessels prior to a description of the muscles, which are such deciding factors in the relationships of these structures. Similarly, in the abdomen, the discussion of the peritoneum should be placed before the description of the viscera, instead of at the end.

The section on ossification and epiphyses is the best in the book, and is illustrated by some excellent diagrams.

A few errors and omissions can be detected. For example, on p. 257 the word "stomata" is misspelt. Again, in the distribution of the deep branch of the ulnar nerve given on p. 16, the short muscles of the little finger are left out.

The book is printed in large clear type, and is excellently bound, but the illustrations are on the whole disappointing. Some of them are rather crude, and others are too much overburdened with detail—a confusion of vessels, nerves and tendons in black outlines. The descriptions are attractively written and very readable, and there is a useful and comprehensive index. JOHN CAMERON

Lee's Microtome's Vade-Mecum. Edited by J. Bronto Gatenby, M.A., Ph.D. (Dubl.), B.A., B.Sc., D.Phil., D.Sc., etc., and others. 710 pages, 9 illustrations. Price \$7.50 P. Blakiston's Son & Co., Philadelphia, 1928

As a reference book on methods employed in microscopical anatomy in the various branches of biology this work is very well known. In this new edition there has been an enlargement of the embryological, cytological, protozoological and entomological sections. New sections have been added by Dr. Robert Chambers and Dr. W. R. G. Atkins. The protozoological section has been rewritten by Dr. Helen Pivell Goodrich, and Dr. Greenfield has added new material to the sections on the nervous system.

This work has passed through numerous editions with considerable increase in material and a broadening of its scope. As a handbook of reference it has considerable value and forms a valuable aid to the laboratory worker. Methods are often given with considerable brevity, but references to the original articles are placed conveniently in the text after the author's names. In the chapters which cover subjects with which the reviewer is particularly familiar he feels there is a tendency to include many old and useless methods which could well be omitted, and thus allow more space for the better, well recognized techniques which are generally employed.

T. R. WAUGH

Liver and Liver Extracts
in the treatment of
PERNICIOUS ANAEMIA

The specificity of the Minot-Murphy liver diet has been conclusively demonstrated in the therapy of pernicious anaemia. In many cases, however, it proves impracticable to keep patients on a diet rich in liver, but in these cases the oral administration of specially prepared liver extracts will achieve the desired results

Liver Extract prepared according to a method devised by Cohn and his associates at the Harvard Medical School is available from the Connaught Laboratories, *either as a powder or as a solution*, in packages each of which contains the extract derived from approximately five pounds of liver. It is of equal therapeutic value in either form, but from a practical point of view the powder has certain obvious advantages over the liquid

*Information relating to the use of Liver
Extract in the Treatment of Pernicious
Anaemia will gladly be sent to any
Physician or Hospital upon request*

Fresh Yeast *as a* Preventive *of certain* Post-Operative Disorders

AN ever-present problem in the case of patients who have undergone operations is the prevention of disorders of the gastro-intestinal tract. That intestinal putrefaction constitutes a real menace to recovery is well known. Especially at such a time is recourse to irritating drugs to be avoided as far as possible.

A leading Belgian surgeon, commenting on this problem, says

"To regularize the digestion of patients upon whom I have operated, especially those affected with chronic colitis or attacks of biliousness, I have found yeast advantageous and have used it for more than twenty-five years.

"Yeast, by reason of its absolute harmlessness, is a remedy of the first rank. Its wealth of vitamin B adds greatly to its food value."

AMERICAN physicians and surgeons do not require this confirmation from abroad of a health prescription long and favorably known to them through their own experience. The place of fresh yeast in therapeutics is today as firmly established in America as it is in Europe.

Even in the case of hospital patients not known to be suffering from gastric or intestinal disturbances there is a growing tendency among the profession to prescribe the regular eating of yeast as a *preventive* measure, in order

to forestall the tendency to constipation which so frequently arises from the enforced inactivity of patients confined to their beds.

Fresh yeast exerts a gently stimulating effect on peristalsis, and tends to produce stools of proper bulk and moisture content. Unlike cathartics, it is non-habit-forming and non-irritating to the tender intestinal walls. As opposed to dried or killed yeast, fresh yeast contains millions of viable, *active* cells.

Yeast stimulates the flow of gastric juice, increases the appetite and tends to overcome any tendency to biliousness. Thus, as well as through its well-established ability to induce a marked leucocytosis, yeast markedly aids the hospital patient's recovery.

PHYSICIANS usually suggest three cakes daily, one before each meal or between meals plain, or in water, hot or cold—or any other way the patient prefers. For stubborn constipation it is most effective when suspended in hot water (not scalding), before each meal and at bedtime.

Fresh yeast, being a food, should of course be eaten regularly and over a sufficient period of time.

A copy of the latest brochure on yeast therapy, containing a bibliography of articles and references on the subject, will gladly be mailed on your request. The Fleischmann Company, Dept 474, 208 Simcoe St., Toronto, Ont.

A NERVE FOOD AND TONIC THAT BUILDS NEW TISSUE

Phospho-Lecithin, Wampole, is Actual
Food for the Nervous System

Contains in most effective combination six elements of proven value as nerve nutriment. Calcium, Potassium and Strychnine Glycerophosphates, Lecithin and Avenin

Phospho-Lecithin, Wampole is indicated in nervous prostration, nervous debility, sexual impairment, nervous excitement, hysteria, insomnia, and as a restorative tonic after typhoid fever, pneumonia, influenza and la grippe

The Tycos Office Type **Sphygmomanometer**

IN the periodic health examination determination of blood pressure is an important point. The Tycos Office Type Sphygmomanometer, because of its peculiar construction, renders invaluable service in this work. In addition to accurate blood pressure readings much can be learned of the arterial wall consistency by study of the single systole.

The Tycos Office Type Sphygmomanometer illustrated has a 6" silvered metal dial, long black hand and heavy case. It is designed for use on table desk or it may be fastened directly to the wall. Its larger size enables much more accurate observation than is possible with the small pocket type model.

The new carrying case makes a convenient method of carrying and storing the Office Type Sphygmomanometer. Makes the instrument available for bed side work.

A Knowledge of Shoes is Helpful to Every Physician

In a recent address to the Medical Profession, a prominent physician deplored the lack of interest being shown by his profession in the treatment of foot ills, and advised every physician to include these cases within the scope of his practice

Diagnosis will often reveal that misalignments in the foot structure are the cause of illness Let a cuneiform, scaphoid, metatarsal or anyone of the twenty-six bones in the foot slip out of its proper position, and a reflex action, sometimes far removed from the feet, will occur

That shoes are the principal cause of modern foot troubles, is conceded Badly shaped lasts, excessive heel heights, crowding, straining, etc, all borne with a suppressed sigh of pain, can be blamed for fallen arches, crippled toes and various foot deformities which, individually or collectively, upset normal balance, proper posture and good health

When a diagnosis shows that such a condition exists, a change to shoes that provide normal freedom and corrective support is indicated In the opinion of leading orthopedists who have studied shoes, the Cantilever is ideal for such cases

Cantilever Shoe

(For Women, Men and Children)

Just a few of the scientific features that recommend the Cantilever Shoe (standard models) for foot correction Adequate support for the arches, a flexible, muscle exercising shank (arch) which fits the foot arch perfectly, combination lasts, correctly balanced heels of moderate height, straighter inside line, room for all the toes, full tread across the ball

The fine quality and good appearance make the Cantilever an exceptional value exclusive of its healthful features

It is no wonder that the physician not only recommends Cantilevers to his patients but wears them for his own benefit

If the heart beat ten times a second

— its image on a PATTERSON FLUOROSCOPIC SCREEN would still be clear and sharp

Highly important among the properties of a fluoroscopic screen is freedom from lag. Absolutely essential when the radiological diagnostician is examining moving organs such as the heart, this quality is also desirable when fixed bones and tissues are being studied, as every patient moves slightly under examination.

Of equal importance is freedom from grain. This assures sharp, clear cut outlines and full detail. Furthermore, PATTERSON screens give a brilliant white light presenting images approaching the black and white contrasts to which the eye is most accustomed.

Careful and precise methods of manufacture mean screens that are affected by heat, dampness or pressure or by the continual bombardment of X-rays. PATTERSON SCREENS do not deteriorate with age.

Ninety percent of all fluoroscopic screens in use today are PATTERSONS. Made by pioneers of the industry—a company that makes nothing but X-ray screens—they have achieved a distinction that makes them the choice of leading roentgenologists.

"Your Hearing Shows Daily Improvement"

Both the Doctor and his patient are gratified beyond measure

THE human ear is an extremely delicate organ wherein to apply corrective measures. Science nevertheless has, after careful research, demonstrated quite conclusively that, when indicated, a passive massage of the mobile parts can be safely applied by means of rhythmic air wave vibrations.

In cases of middle ear deafness moreover such massage is demonstrated to have the desired effect, the patient usually regaining ability to hear conversational tones unaided.

THE AUDOTOR produces the proper air wave vibrations under ideal conditions. They are administered through space at varying amplitudes and under complete control, thus providing for any required degree of massage without auditory nerve response. Results are gratifying.

We shall be glad to forward complete particulars upon request.

Gratifying Results in thousands of cases of High Blood Pressure

Pending the determination and correction of the cause of High Blood Pressure, Pulvoids Natrico (High Tension, Brunton-Thrush) has proved its remarkable efficacy not only in reducing immediate symptoms, but also in maintaining vascular tension at a safe level, without reaction, depression or gastro-intestinal disturbance

From the formula of Sir Lauder Brunton to effect vaso-dilatation, with the addition of cardiants suggested by M C Thrush, M D, Ph M, of Central Hospital Especially coated to pass through the stomach intact and to disintegrate promptly in the intestinal tract, thus avoiding gastric disturbance

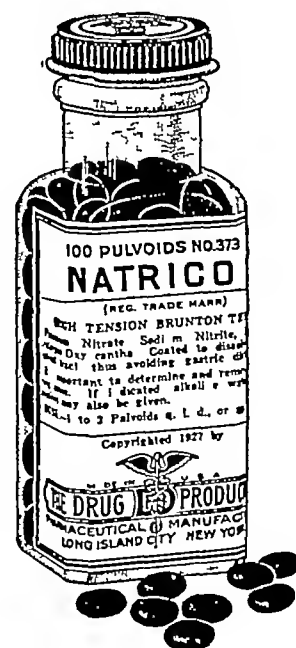

"It is very important that the underlying cause be determined and corrected, employing Pulvoids Natrico as a measure of safety in the interim"

Dose 1 to 3 Pulvoids q 1 d

Service Is What Service Does

The maintenance of forty-one Victor offices in the principal cities of the U S and Canada, all manned by factory trained men, is one of the reasons for satisfied Victor users everywhere. The combination of Victor Quality and Victor Service is to protect and justify your investment in X ray and Physical Therapy apparatus

Local Victor Service is available at

A RECENT incident served to prove how our nation-wide service organization can respond to a severe test

The Victor office at Washington, D C., was informed by the Navy Department that service was desired on Victor X-ray apparatus installed on the Airplane Carrier U S S *Lexington*, then lying at San Pedro, Calif., 3000 miles away. Quick action would be necessary, as the ship might be sent to sea at any moment. The message was flashed to the manager of the Victor Branch Office at Los Angeles, and on the same day a trained service man reported at San Pedro, leaving them with their outfit operating at 100% efficiency

For years the Victor organization in its publicity has repeatedly referred to *Victor Service* as one of the advantages enjoyed by users of Victor products. While the use of the word *service* is relied upon by many organizations to perform miracles toward winning favorable consideration for a product, any gratifying results can emanate only through the actual rendering of the service, when the need for it is urgent and the situation unusually difficult.

Letters in our files from physicians and institutions in all parts of the United States and Canada commend the Victor organization on making good its claims for *Victor Service*

Among the Results of Constipation

Distended and sagging cecum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxemias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL, combining three essential actions lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted feces,

generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol assists the organism to clean house in its own way, by restoring *normal peristaltic function*.

The dependability of Agarol has definitely enlisted the interest of the medical profession who in most cases of acute or chronic constipation, successfully prescribe Agarol — one tablespoonful on retiring

*A Liberal Quantity For Trial
To Physicians*

WILLIAM R. WARNER & CO., LTD.

Agarol is the original Mineral Oil — Agar Agar Emulsion (with Phenolphthalein) and has these advantages:

Perfect emulsification, stability, pleasant taste without artificial flavoring, free from sugar, alkalies and alcohol, no oil leakage, no griping or pain, no nausea, not habit forming.

NEO-SILVOL

(Silver Iodide in Colloidal Form)

Non-Irritating · Stainless · Efficacious

NEO-SILVOL is an active germicide containing 20 per cent of silver iodide in a soluble gelatin base.

When tested against the gonococcus, Neo-Silvol has a phenol coefficient of 20, against the streptococcus and the staphylococcus it is as strongly germicidal as pure phenol. It does not stain the skin or clothing and has considerable penetrating power.

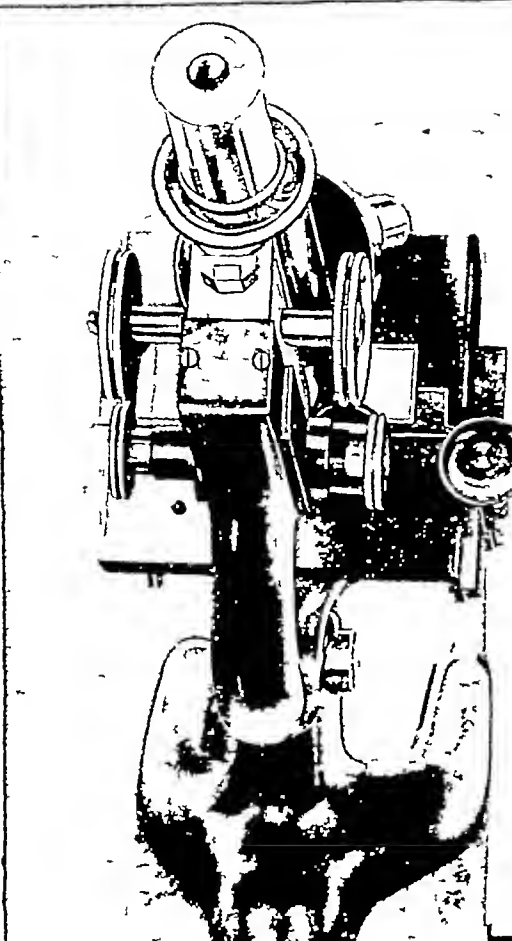

Neo-Silvol has been successfully employed in the prophylaxis and treatment of gonorrhea and may be used to advantage in the early treatment of "common colds" and other catarrhal infections of the nasopharynx. In conjunctivitis it acts promptly and may also be utilized in inflammatory affections of other accessible mucous membranes.

Neo-Silvol is supplied in 1-oz. and 4-oz. bottles of the granules, in 6-grain capsules, bottles of 50, as a 5 per cent Ointment in 1-drachm tubes, and as 5 per cent Vaginal Suppositories in boxes of 12.

Notice that from the eyepoint position the mechanical stage takes up an exceedingly small amount of space. That leaves the stage itself free for the manipulation of the specimens.

Then too, the rack is directly attached to the bearing slide and the drawing contact is exactly in the center of the bearing. This arrangement eliminates side pull and strain.

Send for our booklet "6 Points of Perfection" which gives you other important features.

Bausch & Lomb Optical Co
632 St. Paul St. Rochester N Y

CYSTITIS AND PYELITIS

In cystitis, whether acute or chronic, the distressing symptoms such as pollakiuria and dysuria are alleviated and there is a prompt reduction in the pus content of the urine upon the oral administration of Pyridium in doses of 0.1 to 0.2 gm. three times a day. When necessary to employ vesical instillations a 0.2 to a 0.3 per cent solution may be safely employed. In the more acute or recent inflammations the instillations may be pushed to the limit of tolerance.

The same properties of Pyridium that account for its efficacy in cystitis, make it of special value in the treatment of pyelitis and pyelocystitis caused by infection. The remedy is valuable as a prophylactic especially in checking ascending infections and in the treatment of pyelitis of pregnancy and the pyelitis which occasionally follows operative procedures.

There is usually a prompt recession of the acute symptoms such as dysuria, polyuria and hematuria. With the reduction of pus any accompanying fever or symptoms of toxemia are lessened. The usual attention should, of course, be paid to elimination and to dietetic and hygienic measures as indicated. Pyridium does not change the reaction of the urine and is itself equally effective in either acid or alkaline urine. In kidney disorders that are amenable to medical treatment the only conditions in which the remedy is contraindicated is uremia and serious non-progenic disorders. The dosage requirements are the same as for cystitis. (Merck & Co, Rahway, N.J.)

INHALATION TREATMENT

One of the simplest and most rational of the many applications available for the treatment of rhinitis, laryngitis, and other affections of the nose and throat resulting in congestion or swelling of the mucous membrane, is Adrenalin Inhalant, Parke, Davis & Co. This preparation contains in a vegetable oil base, Adrenalin in the same percentage as that contained in the standard aqueous solution—1 to 1000. The effects of Adrenalin inhalant are prompt but prolonged, for the reason that the Adrenalin is released slowly from the oil. Thus the patient gets a gradual and continued astringent action from the application of the inhalant. While it is usually employed full strength, some practitioners prefer to dilute it with three or four parts of olive oil or cottonseed oil, it does not mix well with mineral oils. The use of Adrenalin Inhalant is advised in connection with some bland yet efficient antiseptic—one of the silver preparations, for example.

The best instrument we have ever seen for applying Adrenalin Inhalant is what is known as the Glaseptic Nebulizer made by Parke Davis & Co.

Calcium in Acid Form

IMPORTANT to PHYSICIANS ESPECIALLY GYNECOLOGISTS

Progressive Gynecologists and Physicians in general will welcome the advent of Ponde Tampon which offers an easy safe and thorough method of vaginal and uterine medication. It combines the medicinal function of a vaginal suppository with the mechanical support offered by a correctly shaped tampon ensuring the continued application of the medicament to the diseased areas and at the same time furnishing the necessary support.

The various treatments to which the tampon is adaptable will be at once apparent to the physician, but lacerations leucorrhoea gonorrhoea prolapse post-operative and post-confinement treatment, and uterine hemorrhage are some of the conditions in which Ponde Tampon offer new and most effective treatment. There are many unique points of advantage in treatment by Ponde Tampons.

Ponde Tampons are packed in six tampons to a box and are made in the following medication

INDOLENT ULCERS

when not due to specific pathogenic organisms
become largely a question of impediment of
circulation and faulty nutrition

ANTIPHLOGISTINE, applied hot, dilates the capillaries, brings more blood to the area, stimulating thereby local circulation, resulting in better tissue nutrition as well as hastening the absorption of assimilable exudate. The continuous moist heat generated *and maintained* by this plastic, analgesic dressing is non-irritating and may therefore be applied over a long period of time with complete absence of toxic action.

Antiphlogistine, containing 45% c p glycerin, can be relied upon as a safe antiseptic agent, exerting a sedative action upon the cutaneous nerves, promoting local metabolism, a marked phagocytosis, increasing the number of red cells and stimulating granulation.

The observations of leading practitioners confirm the fact that this procedure does much to shorten the chronicity and suffering in these cases, and that coupled with rest and elevation.

Lister Bros, Inc, New York, U S A

In our temperate climate few babies get enough sunshine. Good cod-liver oil, with its abundant supply of Vitamin D is needed to aid in the growth of good bones and sound teeth.

Care maintains the high vitamin content of this cod-liver oil

The vitamin potency of cod-liver oil is variable and easily affected by exposure to air, therefore, your patients are only sure of receiving a full supply of both Vitamin A and Vitamin D when they use an oil which is protected against oxidation, tested for vitamins, and guaranteed.

In the preparation of Squibb's Cod-Liver Oil, every precaution is taken to ensure high vitamin content. The livers are carefully selected, the oil is refined under anaerobic conditions and is dehydrated to prevent deterioration in the oil, especially in its vitamin content.

Before bottling, the oil is further guarded against oxidation by being charged with carbon dioxide by which the oil is protected through a normal period of use by the covering film of gas which rises to fill the space in the top of the bottle after each spoonful is taken.

New!

A mint-flavored cod-liver oil by Squibb

For those who prefer it, there is now a new cod liver oil—mint flavored. Just as effective as the plain oil, yet easy and pleasant to take. For growing children, for expectant and nursing mothers, Squibb's Mint flavored Cod Liver Oil is an agreeable supplementary source of the necessary Vitamins A and D.

Physiological tests show Squibb's Cod-Liver Oil to have a Vitamin A content of not less than 50,000 United States Pharmacopœia Units in each 100 grams.

The Vitamin D content of Squibb's Cod-Liver Oil is determined by its efficacy as a specific against rickets. Tests on laboratory animals show that its content of the antirachitic Vitamin D is amply adequate to promote the assimilation and utilization of calcium and phosphorus.

This vitamin content is guaranteed. You can, therefore, prescribe Squibb's Cod-Liver Oil for the regular use of your patients with the assurance that they will receive the expected quantity of vitamins. At all drug stores.

E. R. SQUIBB & SONS OF CANADA LIMITED

468 King St. West - - - Toronto, Canada

Produced, Tested and Guaranteed by E. R. Squibb & Sons, New York Manufacturing Chemists to the Medical Profession since 1858

Are you taking advantage of Knox Sparkling GELATINE

A valuable dietary adjunct for diabetic patients?

BECAUSE plain unflavored gelatine blends perfectly with all fruits, vegetables, meat and fish, it is ideally suited to lend variety and palatability to the diabetic diet. Portions too small to serve alone can be made into satisfactory dishes with the addition of Knox Sparkling Gelatine.

With Knox Sparkling Gelatine a number of pleasing variations can be introduced into the diabetic diet—dishes that have high protein or fat value, are appetizing, and impart a sense of satiety to the patient. Made plain and pure—unbleached, without flavoring, coloring or sugar content, Knox Sparkling Gelatine is an ideal food for the purpose. These qualities, also, make it a desirable means of lessening the monotony of liquid and soft diets in general.

In infant feeding, the protective colloidal ability of Knox Sparkling Gelatine in overcoming imperfect milk digestion has long been known. Exhaustive tests have proved that the addition of 1% of pure, unflavored gelatine to cow's milk tends to prevent regurgitation, gas, colic, diarrhea, and malnutrition. In fact, Downey has demonstrated that the addition of gelatine increases the available nourishment of milk mixture, by about 23%.

Knox Sparkling Gelatine is manufactured by a concern with 40 years of experience in making this one product. From raw material to finished product, every step in its manufacture is under constant chemi-

cal and scientific control. The most sanitary conditions prevail throughout the factory.

Valuable booklets on dietetics available

The booklets included below have been prepared by recognized dietetic authorities. They contain important data on the use of Knox Sparkling Gelatine in the various diets, together with recipes for a variety of tempting, appetizing dishes. Surgeons, doctors, dieticians, and members of hospital staffs will find them valuable references. Check those you would like to have and mail us the coupon.

CAUTION!

All gelatines are not alike. Many have added acid, flavoring and coloring matter. In the form of ready prepared desserts they contain as high as 85 per cent carbohydrates.

Knox Sparkling Gelatine is a protein in its purest form particularly suitable where carbohydrates and acids must be avoided. It contains more than 80 per cent pure protein (4 calories per gram).

Specify Knox when you prescribe gelatine and you will protect the patient from brands unsuitable for his dietary purposes.

CONTRIBUTIONS

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this *Journal*

COPYRIGHT Matter appearing in the *Journal* is covered by copyright but, as a general rule, no objection will be made to the reproduction in reputable medical journals of anything in these columns, provided proper credit be given

MANUSCRIPTS Should be typewritten, double spaced, and the *original* copy submitted to the respective Editorial Boards

ILLUSTRATIONS: Will be paid for by us when satisfactory photographs or drawings are supplied by the author. Negatives are not acceptable. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct and preferably black and on glazed paper, drawings should be made in india ink on white paper. For illustrations requiring cuts the best copper plate is used and all are printed on glazed paper. The *Journal* reserves the right to return photographs which are not satisfactory. Contributors are respectfully requested to limit illustrations to such as are absolutely necessary.

REPRINTS TO CONTRIBUTORS These may be ordered from the printers upon the form submitted with the galley proof.

ADVERTISEMENTS

First advertising forms go to press thirty days in advance of the date of issue. In forwarding copy, time must be allowed for setting up and submitting proof. Advertising rates on request.

N.B.—We exclude from our columns all known questionable advertisements and appreciate notification from our readers relative to any misrepresentation.

CLASSIFIED ADVERTISEMENTS are payable in advance. To avoid delay in publishing, remit with order. Advertisements under the following headings cost \$2 00 for each insertion of 40 words or less, additional words 5 cents each.

WANTED Apparatus, Assistant, Books, Location, Partner, Partnership, Situation

FOR SALE: Apparatus, Practice, Sanitaria, Drug Stores

At the Menopause

The distressing symptoms that so often accompany the climacteric, but more particularly the aggravated symptoms of the artificial menopause, are frequently controlled by the administration of

LUTEIN TABLETS, H W & D.
LUTEIN SOLUTION AMPULES, H W & D

The choice of the medication depends, of course, on the judgment of the physician as to whether oral or hypodermatic administration is indicated. Both products represent the

CORPUS LUTEUM OF THE SOW

unmodified by treatment with solvents or by exposure to temperatures above animal body heat in the drying process. All separation of extraneous matter is made by mechanical means and all drying is *in vacuo*. The unaltered *corpus luteum* should, therefore, be presented in our products and clinical experience with them should demonstrate their therapeutic activity.

Ovarian dysfunction as evidenced in dysmenorrhea and amenorrhea is also an indication for Lutein medication, and if the diagnosis of such dysfunction is reasonably well established, definite therapeutic results may be expected.

WHOLE OVARY TABLETS, H W & D
OVARIAN RESIDUE TABLETS, H W & D

are also offered for those who prefer, for certain indications, the use of the whole gland or of the residue remaining after corpus luteum separation.

When the Enfeebled Stomach Revolts

at drugs and emulsions, and yet a reconstructive tonic is essential, prescribe Guiatonic.

A carefully balanced general systemic tonic, Guiatonic possesses the unusual additional advantage of being acceptable to the most delicate digestive system, and stimulating the processes of food assimilation.

Indicated wherever a tonic is needed.

Guiatonic

A generous trial quantity free upon request William R Warner & Company, Ltd, Manufacturing Pharmacutists since 1856 727 King St West, Toronto, Ont

A palatable preparation of special salts of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. It contains no narcotics.

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

Diseases of the Gastric Tract

IN the dietary of gastritis, gastric ulcer and other digestive disorders "Ovaltine" is largely used and with conspicuous success. It can be well adapted to individual requirement, is well tolerated by the patient and is preferred to the routine diet.

Given in conjunction with milk "Ovaltine" increases its nutritive power, doubles its digestibility and renders it far more acceptable to the patient.

"Ovaltine" Tonic Food Beverage is a highly concentrated extraction of malt extract, milk and eggs, with a cocoa flavouring. Its content of easily assimilable sugars and its high diastatic power render it a nutrient of unexampled value in all conditions where the need of a complete food in an easily digested form is indicated.

One cupful of "Ovaltine" prepared according to the directions yields more nourishment than 12 cupfuls of beef extract or 3 eggs.

There is a Greater Measure of Safety in Mead's Dextri-Maltose

THE MEAD POLICY

MEAD'S infant diet materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

Comparative Sizes
of English
and American
Tablespoons

Nothing tells more graphically the story of greater safety—the freedom from nutritional disturbances in infant feeding that goes with the use of Mead's Dextri-Maltose than the circumstances surrounding its introduction in England.

It had been used there for over three years as a carbohydrate addition to cow's milk mixtures. During this period results from its use had been quite satisfactory. In England, as in America, it had been prescribed by the level tablespoonful.

After three years of good results a prominent English pediatricist pointed out that the British tablespoon is twice the size of the American. The English level tablespoon holds $\frac{1}{2}$ oz. of Dextri-Maltose, the American $\frac{1}{4}$ oz. Where 6 American tablespoons had been prescribed in 24 hours the infant was actually taking 12 or, in other words, instead of the usual $1\frac{1}{2}$ oz. per 24 hour period, the carbohydrate addition had been doubled to 3 ozs.

Despite the continued use of twice the usual amounts of Mead's Dextri-Maltose in England, nutritional disturbances were a rarity. It is doubtful if any other carbohydrate could have been used in such excessive quantities with equal immunity from serious results.

Royal College of Surgeons England

EXAMINATIONS IN CANADA

First Professional Examination for the Diploma of Fellow

TORONTO - JULY or AUGUST, 1929*

Arrangements have been completed by the Canadian Medical Association whereby the Royal College of Surgeons of England, will conduct in Canada the "Primary" examination in Anatomy and Physiology leading to the

FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

The examinations, both written and *viva voce*, will be held by two examiners in each subject sent from England, and one assessor in each subject who is resident in Canada, but appointed for the purpose by the Royal College

A candidate for examination must deliver to the General Secretary of the Canadian Medical Association prior to April 1, 1929, for transmission to the Secretary of the Royal College of Surgeons, the following certificates

- 1 Of matriculation at a "recognized University",
- 2 Of having completed the examinations in Anatomy and Physiology for degrees in Medicine and Surgery of a "recognized University",
- 3 Of having dissected in a "recognized" Medical School or Schools during six terms or eighteen months,

Note—Dissections during the regular vacations will be accepted provided the certificate shows that they have been performed under the superintendence of an authorized teacher in a recognized Medical School

- 4 Of having attended in a "recognized" Medical School or Schools —
 - (a) a course of lectures on Anatomy during two terms,
 - (b) a course of lectures on Physiology during two terms,
 - (c) a course of Experimental Physiology,

Note—It is meant that the learners themselves shall individually be engaged on the necessary experiments manipulations etc but it is not hereby intended that the learners shall perform vivisections

- (d) a course of Chemical Physiology,
- (e) a course of Histology

The fee for examination or re-examination shall be \$100 00

The Final Examination for the Fellowship is held only in England and candidates for admission to that examination must have passed the Primary Examination and hold the Diploma of Member of the Royal College of Surgeons of England or have held for not less than four years a degree of a recognized University registrable on the Medical Register of Great Britain.

Scientific control in local applications

Have all kinds of ULTRA-VIOLET the same effect?

NO, for some will cure rickets—others will not—some will sunburn—some won't. The reason for the difference between the ultra-violets is the wave length. Clinical evidence suggests strongly that rays from mercury vapor quartz lamps are of considerable value in certain forms of disease.

"Ultra-violet light from the air-cooled mercury vapor quartz lamp is a specific in tetany, rickets, and spasmophilia, and is very valuable as a general tonic in depressed bodily states such as anorexia and some cases of anemia, and in poor nutri-

tion. The Atlantic Medical
Vol XXXI, No 8, May,
p. 537-542

The KROMAYER LAMP is for irradiating all local areas and the successful application of rays to those conditions indicated for which it is

The Vital Element of the KROMAYER LAMP

If there were no other advantages in the KROMAYER LAMP—if the mechanical excellencies that make for scientific precision and utmost convenience were eliminated—there would still remain one strong reason for its use—the HANOVIA Burner.

This burner is of the entire quartz mercury anode type, and is manufactured completely by Hanovia.

Each burner must pass a rigid test in the Hanovia laboratories, to insure the highest intensity and the longest service.

The economy of the HANOVIA Burner is apparent in its low consumption of current.

Further eventual economy is afforded by the ingenious construction which permits the repair of old or broken burners.

Diversification Insures Investment Stability

The most important thing that can be done to protect and stabilize an investment fund is to divide the risk both geographically and amongst various types of securities

The breadth of National City offerings simplifies diversification. Whether you are investing for the first time, or adding to present holdings, our lists will always provide a variety of issues from which to choose, each one of which has been carefully investigated and is recommended as a good investment in its class—Government, Municipal, Railway, Public Utility, Industrial, and Foreign Bonds

Our advice as to the securities best suited to your requirements has back of it the broad experience of our organization in meeting the needs of thousands of other investors, and is governed by your present holdings and financial circumstances. Correspondence is invited. Our facilities are at the disposal of investors everywhere, irrespective of the amounts available for investment

BUSINESS REPORT OF THE FIFTY-NINTH ANNUAL MEETING OF THE CANADIAN MEDICAL ASSOCIATION HELD IN CHARLOTTETOWN, P E I

June 18-23, 1928

THE first session of Council of the Canadian Medical Association, for the annual meeting of 1928, was held in The Prince of Wales College, Charlottetown, P E I, on Monday morning, June 18th, at 10 30 o'clock. The following members were in attendance —

Doctors G H Agnew, Toronto, L J Austin, Kingston, Gordon Bates, Toronto, A T Bazin, Montreal, G S Cameron, Peterborough, W N Cochran, Mahone, J W Crane, London, G R Cruickshank, Windsor, J D Curtis, St Thomas, G F Dewar, Charlottetown, C A Donkin, Bridgewater, F J Farley, Trenton, W M Fisk, Montreal, J G FitzGerald, Toronto, A G Fleming, Montreal, Duncan Graham, Toronto, J F Haszard, Kimberley, Geo Hall, Montreal, T G Hamilton, Winnipeg, J S Hart, Toronto, W B Hendry, Toronto, E V Hogan, Halifax, W P Hogarth, Fort William, J C Houston, Charlottetown, S R Jenkins, Charlottetown, T M Leask, Moose Jaw, T H Leggett, Ottawa, J Ross Millar, Ottawa, H B Moffatt, Ottawa, L R Morse, Lawrencetown, J H Mullin, Hamilton, H H Murphy, Kamloops, A R Myers, Moncton, J K McLeod, Sydney, H McLean, Regina, H E MacDermott, Montreal, J G MacDougall, Halifax, J B McKenzie, Chatham, J R Nugent, St John, John Oille, Toronto, G R Peterson, Saskatoon, W L Robinson, Toronto, F W Routley, Toronto, T C Routley, Toronto, H Smith, Winnipeg, F N G Starr, Toronto, J Stevenson, Quebec, John Stewart, Halifax, M T Sullivan, Glace Bay, P H Thorlakson, Winnipeg, G C VanWart, Fredericton, S L Walker, Halifax, C A Warren, Toronto, R E Wodehouse, Ottawa, W A Wilson, Edmonton, F Woodhall, Hamilton, Geo S Young, Toronto

In a brief address, Dr S R Jenkins, President-Elect of the Association, welcomed the visiting members to the City of Charlottetown

REPORT OF THE COMMITTEE ON PERSONAL ARCHIVES

With the members of Council standing, the General Secretary read the report of the Committee on Personal Archives —

Mr Chairman and Members of Council —

Meetings of the Central Committee have been held in Montreal from time to time during the past year

In January, 1927, twenty-eight hundred questionnaires were mailed to members of the Association and of these, twelve hundred and thirty three have been returned completed. An alphabetical list of the completed papers has been prepared

A second request for the return of the questionnaire has been mailed to those members who have not yet completed the form, and the Provincial members of the Committee have been requested to speed up these returns when possible

It has been suggested that new members should be asked to fill in the questionnaire on joining the Association

During the year of 1927 the Committee regrets to report the death of the following members —

Dr A H Adams, Toronto, Ont
Dr J E Affleck, Nelson, B C
Dr Robt Archer, Port Perry, Ont
Dr A C Campbell, St Thomas, Ont
Dr B H Champion, Vancouver, B C
Dr W G Daw, Owen Sound, Ont
Dr D R Dunlop, Calgary, Alta
Dr J C Elliott, Chilliwack, B C
Dr D D Ellis, Listowel, Ont
Dr W D Ferris, Edmonton, Alta
Dr A E G Forbes, Lunenburg, N.S.
Dr Gerald W Grant, Halifax, N.S.
Dr T R Hanley, Toronto, Ont
Dr P J Kirby, Guelph
Dr C D McCulloch, Wellington, Ont
Dr J J McFadden, Stony Mountain, Man
Dr V E McKay, Edmonton, Alta
Dr Gordon E McLean, Fredericton, N.B.
Dr Campbell Myers, Toronto, Ont
Dr W R Riddell, Norwood, Man
Dr S J Rothwell, New Westminster, B.C.
Dr M Sharp, Tilbury, Ont

Dr J R Stanley, St Mary's, Ont
 Dr H C Steeves, New Westminster, B C
 Dr F W Stockton, Calgary, Alta
 Dr W E Struthers, Toronto, Ont
 Dr T A Swift, Abbotsford, B C
 Dr Oscar L Taylor, Mortlach, Sask
 Dr Gordon E Thompson, Hardisty, Alta
 Dr Jas Warburton, Charlottetown, P E I

All of which is respectfully submitted

C F WYLDE,
 Chairman

Approved

REPORT OF THE EXECUTIVE COMMITTEE

The Report of the Executive Committee was discussed clause by clause, as follows —

Mr Chairman and Members of Council —

Three meetings of your Executive Committee have been held during the year. The Sub-Executive Committee met on two other occasions.

As most of our activities are discussed in the many reports presented herewith, it is unnecessary for your Executive Committee to report at great length. We respectfully direct your attention to the following —

1 — COMMITTEE ZONING

The principle of zoning the Committees of the Association, as adopted at our annual meeting in 1926, was adhered to during the past year. In our opinion, interest in the many branches of our work has thereby been sustained and increased. We would recommend that the plan be continued.

Approved

2 — SUN LIFE ASSURANCE COMPANY

It is indeed a matter of much gratification to your Executive Committee to be able to report a third grant of \$30,000 from the Sun Life Assurance Company of Canada to carry on our extra mural post-graduate work for another year. The report of the Post-Graduate Committee indicates that the work has been progressively successful. That we were able to initiate and continue for a period of three years this unique post-graduate plan, covering all Canada, is due to the marvellous generosity of our benefactors. No doubt Council will be glad again to express to the Sun Life Assurance Company our sincere thanks for their financial support.

Approved

3 — DEPARTMENT OF HOSPITAL SERVICE

Growing out of the recommendations embodied in the report of the Committee on Hospital Efficiency, as presented to our annual meeting last year, your Executive Committee approached the Sun Life Assurance Company to ascertain if they would be willing to extend their financial support to the Association to cover the cost of maintaining a Department of Hospital Service. We were asked to present a plan accompanied by a budget. This we were glad to do, indicating that the Department, in our opinion, could be successfully operated at a cost of \$15,000 a year. It is now common knowledge that the Company which so generously financed our post-graduate plan was good enough to make a further grant to our Association of \$15,000 a year, bringing their total annual grant up to \$45,000. Council will be glad to have this opportunity of further expressing to the Sun Life Assurance Company our great appreciation of their generosity.

Your Executive Committee gave much thought to the organization of this Department. We believe we were

fortunate in securing the services of Dr G Harvey Agnew as Associate Secretary of the Association to take charge of this new work. Although Dr Agnew has only been with us for five months, his report presented herewith indicates that the future holds much promise for a real service to the hospitals and the people of Canada through the Department of Hospital Service of the Canadian Medical Association.

Approved

4 — MEMBERSHIP

At the close of the year 1927, our membership stood as follows —

British Columbia	335
Alberta	248
Saskatchewan	283
Manitoba	349
Ontario	1,440
Quebec	542
New Brunswick	112
Nova Scotia	153
Prince Edward Island	43
Newfoundland	14
Miscellaneous	252

Total 3,771

At time of going to press, our membership stands at 3704, with 314 fees in arrears, the majority of which are hopeful. As membership remittances continue to reach our office daily, it is anticipated that the showing for 1928 will compare favourably with 1927. It must be pointed out to Council, however, that the place of meeting has a definite bearing upon membership, and, whereas we had an attendance at the annual meeting last year approximating 2,000, it is unlikely that our membership figures this year will measure up to 1927.

Approved

5 — COLLECTION OF FEES

It has been suggested by one of our members resident in Western Canada that the Association should inaugurate a plan of fee collection during the autumn months to cover the ensuing calendar year. It is said that the flow of money in Canada reaches its height in the autumn, which might make it easier for many members to meet their obligation to the Association at that time. On the other hand it will be admitted that the financial demands made upon all of us appear to be heavy about Christmas time and the New Year. The suggestion is passed to Council for consideration.

In connection with the above, the following recommendation was submitted to Council for consideration:

"That accounts for membership fees to cover the succeeding year be sent out in October, but that, before definite action is taken, a ruling be obtained from the Committee on Constitution and By-Laws."

Having been assured that there is nothing in the existing Constitution and By-Laws to prevent such a change being made, the following resolution was passed —

"That, henceforth, the membership fees for the ensuing year be collected in the month of October, instead of January as heretofore."

6 — NOTICE OF MOTION

At the present time, membership in our Association is contingent upon membership in one's Provincial Association. Periodically, this regulation has been said to work a hardship upon many of our members and would be members. The subject has been a matter for considerable

discussion in the Executive Committee from time to time. The following notice of motion, presented by Dr A MacG Young, of Saskatoon, is now passed to Council for attention —

"That membership in the Canadian Medical Association be not contingent upon membership in one's Provincial Association, and that our Constitution be so amended"

This proposal has been referred to all the Provincial Associations in Canada, with the following expressions of opinion notified to your General Secretary up to this time —

Provinces in favour of the amendment — Saskatchewan, Alberta, Manitoba and Ontario

Opposed — British Columbia, Quebec and Nova Scotia

Considerable discussion arose with reference to the advisability of allowing membership-at-large in the Canadian Medical Association, the following points being emphasized —

The decisions arrived at by the different provinces are no doubt the result of local conditions

As far as the Canadian Medical Association is concerned, there is no objection to a man being a member of the national Association without first being a member of his provincial Association in such provincial associations as are willing to allow it

There should be a certain amount of uniformity in connection with Canadian Medical Association membership across Canada

The Canadian Medical Association as a national organization should be open to every member of the profession in Canada

There should be continuity of membership in local, provincial and Canadian Medical Associations, in order to establish a strong national organization

Would suggest amending the constitution to permit of membership in the Canadian Medical Association, either with or without membership in a provincial association, according to the expressed desire of the provinces concerned

It was finally agreed that the matter should be referred to a sub-committee, to be named by the Chair, for study and report

The following committee was named —

Doctors A T Bazin (Chairman), H H Murphy, Kamloops, Geo S Young, Toronto, W A Wilson, Edmonton, S L Walker, Halifax, F J Farley, Trenton, J Stevenson, Quebec, G S Cameron, Peterborough, H McLean, Regina, Geo Hall, Montreal, J C Houston, Charlottetown

At a later session of Council, the above committee brought in the following report —

"We do hereby recommend to Council that Clause (a), Section 1, Chapter 1, of the By-Laws be amended to read as follows —

Any physician residing in Canada may be elected by the Council an ordinary member of the Canadian Medical Association, provided that,—

- (a) He is a member in good standing in his Provincial Branch Association, or
- (b) in a local society in Canada, other than or constituent of his own Provincial Association, or
- (c) upon application for membership in the Canadian Medical Association, his name being submitted to his Provincial Association and by them recommended for admission to membership in the Canadian Medical Association, and that a list of the members elected during the year under Clauses (b) and (c) shall be reported by the General Secretary to each annual meeting of Council"

The report of the sub-committee, as outlined above, was approved by Council

7—ANNUAL MEETING

Our President, Dr F N G Starr, accompanied by the Honorary Treasurer, Dr A T Bazin, and the General Secretary had the pleasure of meeting with the profession of Charlottetown in November, 1927, when plans for the annual meeting of this year were thoroughly discussed. Your Executive Committee is glad to report that our colleagues in Prince Edward Island have devoted themselves whole heartedly during the past six months to the task of preparing for the fifty-ninth annual meeting. To all of these gentlemen, and to the ladies associated with them, we desire to express our appreciation and thanks

Approved

8—ANNUAL MEETINGS 1929-1930

At our last annual meeting, Council accepted an invitation to meet in Montreal in 1929

As we are hosts to the British Medical Association at their annual meeting in Winnipeg in 1930, it would appear to your Executive Committee that our meeting for that year should consist of a business session only

Approved

The Secretary reported the receipt of a letter from the Hamilton Medical Society inviting the Association to meet in Hamilton in 1932, also an invitation from the Essex County Medical Society to meet in Windsor, Ont. These letters were ordered to be filed for later consideration

9—BRITISH MEDICAL ASSOCIATION, WINNIPEG MEETING, 1930

During the month of April last, Dr J D Adamson, of Winnipeg, and the General Secretary had the privilege of conferring in England with members of the Council and officers of the British Medical Association with regard to the annual meeting of the British Medical Association to be held in Winnipeg in 1930. The kindly reception accorded the Canadian delegates by their British Medical Association hosts left nothing to be desired. It was evident from the very beginning of the deliberations that the British Medical Association is looking forward with much pleasure to the Winnipeg meeting. It is hoped that the plans which were agreed upon by the Committee for presentation to the British Medical Association Council will be available for consideration at this annual meeting

The General Secretary gave a brief summary of the important points discussed at the conference with the British Medical Association in London

in April, 1928, after which the arrangements, as outlined, were approved by Council, and the details in connection with transportation, etc., were left to the General Secretary to arrange, with the recommendation that, as far as possible, the British visitors be given an opportunity of seeing all Canada.

The British Medical Association having requested that two Vice-Presidents and a Secretary for each Section be nominated in Canada, one Vice-President and a Secretary by the Manitoba Medical Association, and the other Vice-President by the Canadian Medical Association, the following nominations are reported as having been made by the two organizations mentioned —

SECTION	VICE-PRESIDENTS	SECRETARY
<i>Medicine</i>	Dr Chas Hunter, Winnipeg, Dr Kenneth A MacKenzie, Halifax	Dr C R Gilmour, Winnipeg
<i>Surgery</i>	Dr B J Brandson, Winnipeg, Dr F H Mewburn, Edmonton	Dr A P MacKinnon, Winnipeg
<i>Obstetrics and Gynaecology</i>	Dr D S MacKay, Winnipeg, Dr W W Chipman, Montreal	Dr F G McGuinness, Winnipeg
<i>Bacteriology, Pathology, Physiology, Bio-Chemistry</i>	Dr Wm Boyd, Winnipeg, Dr Jas Miller, Kingston	Dr A T Cameron, Winnipeg
<i>Pædiatrics</i>	Dr S G Chown, Winnipeg, Dr Alan G Brown, Toronto	Dr O J Day, Winnipeg
<i>Mental Diseases and Neurology</i>	Dr A T Mathers, Winnipeg, Dr Jas W MacNeill, North Battleford	Dr E C Barnes, Selkirk
<i>Ophthalmology</i>	Dr T H Bell, Winnipeg, Dr I G Campbell, Vancouver	Dr F D McKenty, Winnipeg
<i>Laryngology and Otology</i>	Dr S W Prowse, Winnipeg, Dr H S Birkett, Montreal	Dr G W Fletcher, Winnipeg
<i>Preventive Medicine</i>	Dr A J Douglas, Winnipeg, Dr John A Amyot, Ottawa	Dr T A Pinecock, Winnipeg
<i>Tuberculosis</i>	Dr D A Stewart, Nette, Dr C D Parfitt, Gravenhurst	Dr B H Olson, Winnipeg
<i>Radiology</i>	Dr J C McMillan, Winnipeg, Dr Leo Parizeau, Montreal	Dr F A Smith, Winnipeg
<i>Medical Sociology and History of Medicine</i>	Dr H M Speechley, Winnipeg, Dr J W Crane, London	Dr J C B Grant, Winnipeg
<i>Anæsthesia</i>	Dr W Webster, Winnipeg, Dr Wesley Bourne, Montreal	Dr D C Aikenhead, Winnipeg

Approved

10 — OFFICIAL FRATERNAL DELEGATES

(a) *British Medical Association*

Your Executive Committee learns with pleasure that Sir Lenthal Cheate has been appointed an official fraternal delegate from the British Medical Association to our annual meeting this year.

The following members having indicated that they propose to attend the annual meeting of the British Medical Association in Cardiff this year, your Executive Committee has been pleased to nominate them as our official fraternal delegates,—

Dr J D Adamson, Winnipeg,
Dr Duncan Graham, Toronto,
Dr H S Birkett, Montreal,
Dr W R Campbell, Toronto,
Dr Leonard Murray, Toronto

(b) *American Medical Association*

Your Executive Committee has been pleased to appoint Dr Harvey Smith, of Winnipeg, as our fraternal delegate to the annual meeting of the American Medical Association in Minneapolis.

Approved

11 — PERIODIC HEALTH EXAMINATIONS

Under the auspices of the Committee dealing with the matter of Periodic Health Examinations, distinct progress has been made during the year in regard to the production of a manual and forms to be utilized by the profession in carrying out periodic health examinations. Your Executive Committee would suggest that the whole question of making available physical examinations for those who are apparently well should be given careful consideration. Evidence is before us that some of the insurance companies of Canada would be interested in co operating with the Canadian Medical Association, to the extent of offering physical examinations to many of their policy holders. Detailed information, as available, will be presented to Council when this matter is under discussion.

Discussion on this matter was reserved until later, when the Report of the Committee on Periodic Health Examinations was presented to Council.

12 — MOTOR EMBLEMS

Four years ago, a design was approved by Council for a Canadian Medical Association Motor Emblem. 462 of these motor emblems have been sold to our members in various parts of Canada. During the past year, your Executive Committee was approached by one of the largest medical societies of Canada, suggesting that a change be made in the design of our Motor Emblem, because our present one, although a beautiful design, does not attract sufficient attention to be recognized by the police. An alternative design was suggested by this Society, and is presented to Council at this time for consideration.

It was agreed that a committee composed of Doctors Geo S Young, J S Hart, and H E MacDermott should study this matter and report at a later session of Council. The following report was later submitted by that committee —

"We would respectfully recommend that the motor emblem submitted for examination be adopted as the official motor car emblem of the Canadian Medical Association, with the following provisions —

That a committee of three, including Dr G Harvey Agnew, the Associate Secretary, be nominated by the Chairman of Council, with full power to arrange for the production of the emblem and its distribution upon the application of regularly qualified doctors, through the central office, it being understood

(a) that the emblem shall be registered by the Canadian Medical Association, or given such other legal protection as may be necessary,

(b) that the Committee shall be empowered to make such minor changes in the emblem as they deem fit,

(c) that the cost to members shall be not more than Two Dollars "

Some discussion ensued as to whether the badges should be sold outright, or whether the Association should retain the right to recall a badge if, in their opinion, its use was being abused. It was finally agreed that the report of the Special Committee, as outlined above, be adopted

13—PROVINCIAL CO OPERATION

During the past several years, the Provincial Medical Associations have co-operated both in the East and in the West by utilizing travelling teams of speakers particularly at their annual provincial meetings. Your Executive Committee is glad to report that this plan has again been adopted for this year

14—REFERRED BUSINESS

Communications which have come to hand since the publication of this report will be presented as New Business, or placed before Council for discussion in connection with the reports to which they refer

15—CONCLUSION

From point of view of membership, financial position and wide spread interest, the year 1927 was the most successful in the history of the Association. In the opinion of your Executive Committee, the Canadian Medical Association is constantly improving its position in Canada as a most potent influence in regard to all problems associated with the health of our people

This report would be incomplete without special reference being made to the splendid support which has been rendered the Association by the many Committees and individual members who have so whole heartedly assisted in carrying on our work during the past year. To all such, the Executive Committee, on behalf of Council, desires to express sincere thanks

All of which is respectfully submitted

T C ROUTLEY,

General Secretary

The report of the Executive Committee, as a whole, was approved

REPORT OF THE HONORARY TREASURER

Mr Chairman and Members of Council —

The year 1927, from a financial standpoint has been the most successful in the life of the Association and it is with pleasure that I present the audited statement of Messrs McDonald, Currie & Co. Our excess revenue for the year was \$14,103 82 (twice as much as the largest previously reported, in 1924). Receipts from advertising show an increase over 1926 of \$3,078 96, membership fees and subscriptions of \$5,901 19

The expenditure in 1927 exceeded that of 1926 by \$4,079 08

Assets, consisting of Cash, Accounts Receivable, Investments and Trust Funds amount to \$46,133 82

Liabilities, including Accounts Payable and Prepaid, balance of appropriation to Editorial Board, allocation for Department of Publicity and Health Education, Bonds outstanding and Trust Funds total \$21,091 92, leaving a Surplus Balance of Net Assets of \$25,041 90

The total budget administered during 1927, and including the Post Graduate Fund of \$30,000 00 amounts to \$97,879 38

DR A T BAZIN,

Honorary-Treasurer,

Canadian Medical Association,

University Street, Montreal

Dear Sir —

We beg to report that we have completed an audit of the books and accounts of the Association for the year ended 31st December, 1927, and attach Balance Sheet as at that date, together with statement of Revenue and Expenditure for the year

The Receipts and Disbursements of the General Secretary in Toronto, as shown on a statement certified to by Mr J H Dignam as auditor, have been incorporated in the books

A further grant has been made to the Association for Post Graduate work and a summary of the position of this fund at the close of its fiscal year on 30th September last, as set out in a further statement of Mr J H Dignam, appears on the Balance Sheet

Bad Debts amounting to \$148 56 have been written off

During the year twenty bonds of the Association were redeemed leaving a balance outstanding of \$3,500 00

We verified the cash on hand and in Bank and examined the securities held in your Safety Deposit Box on Investment Account and for trusts

After charging all known expenses the excess of Revenue for the year amounting to \$14,103 82, has been transferred to Surplus Account

We found your books in good order and were rendered every assistance in carrying out our work

Subject to the above remarks we certify that in our opinion the attached Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of affairs as at 31st December, 1927, according to the best of our information and the explanations given to us, and as shown by the books

Yours very truly,

(Signed) McDONALD, CURRIE & Co ,

Chartered Accountants

BOND ISSUE

After redeeming twenty Bonds October 1st, 1927, thirty-five remained outstanding. At the meeting of the Executive Committee on March 20th, 1928, your Committee decided that, in view of the substantial surplus balance recorded for the year and the very remote possibility that the outstanding \$3,500 00 would be further required, this debt be paid off immediately. As the first six months terminated with April 1st the thirty-five Bonds, with accrued interest, were redeemed on that date. This successfully clears off this indebtedness. The whole issue of \$15,800 00 has been paid off within seven and a half years—two and one half years before maturity.

A letter went forward during the first week in April to all members who had been subscribers informing them of the action of the Committee regarding the final thirty-five bonds and the complete redemption of the issue. The letter also contained an expression of thanks from the Executive Committee for the active support members rendered by subscribing to the issue during the crisis in 1921 when it was evident that the future of the Association and *Journal* hinged on the successful outcome of this undertaking.

ITEMIZED STATEMENT OF BOND ISSUE

To Bonds Redeemed	By Bonds Issued		
Oct 1st, 1923	\$1,900 00	1921	\$ 4,000 00
" 1924	1,900 00	1922	11,800 00
" 1925	4,400 00		
" 1926	2,100 00		
" 1927	2,000 00		
Apr 1st, 1928	3,500 00		
	<u>\$15,800 00</u>		<u>\$15,800 00</u>

TRAVELLING EXPENSES OF EXECUTIVE COMMITTEE

This expense account which covers the year from July to July and constitutes 50 per cent of the travelling expenses of members to the meetings of the Committee is the lowest on record and amounted to \$243 69.

SPECIAL FUNDS

Post Graduate Fund

During the past two years cheques in connection with this fund were sent by the Sun Life Assurance Company direct to the General Secretary. It was considered desirable, however, that this and all other monies received and expended in the interests of the Association should be recorded on the Treasurers books. Arrangements have therefore been made whereby monies from all sources are now received by the Treasurer and deposited in the General Fund. Cheques for use of special committees are then issued as funds are required.

A full report on the activities of the Post-Graduate Committee will be given by its Chairman, but a summary of expenses from October 1st, 1926 to September 30th, 1927, according to the audited statement of Mr J H Dignam, is appended.

SUMMARY AS ON SEPTEMBER 30TH, 1927

Balance to be received during 1928	<u>7,500 00</u>
	<u>\$15,000 00</u>
By Grant from Sun Life Assurance Co	<u>\$15,000 00</u>
Lester Club Trust Fund	

At the annual meeting, last June, we reported the total subscriptions to have reached the sum of \$4,971 00. During that month the New Brunswick Medical Society forwarded subscriptions amounting to \$105 00 which brought the total capital to \$5,076 00, the fund being thereby oversubscribed by \$76 00.

The expense account of Sir Charles Sherrington, the Listerian lecturer in 1927, was \$491 77. The interest, which is allowed to accumulate to defray the expenses of the triennial oration was \$446 18 and was therefore insufficient by \$45 59. The Council decided that this debit balance should be paid out of the surplus capital and that all monies on hand in excess of the \$5,000 00 should be carried forward and used for the expenses of the next oration.

The publication of the second Listerian Oration in October, 1927, including 200 reprints with covers to Sir Charles Sherrington and Dr Archibald Young cost \$729 76 which was paid out of the General Fund. Statement of receipts and disbursements to April 30th, 1928, are as follows—

By Total Capital Received	\$5,076 00	
Received from Investments and Bank Interest Dec 1st, 1925 to April 30th, 1928	599 65

In presenting the above report, Dr Bazin recommended that members of the Executive Committee attending meetings other than the annual meeting be reimbursed the full amount of their travelling expenses, provided the total sum thus disbursed for any one year does not exceed \$1,000, and, in the event of this figure being exceeded, that payment be made on a pro-rata basis This was approved

The report of the Honorary Treasurer was approved

REPORT OF THE EDITOR

Mr Chairman and Members of Council —

COLLEGE OF PHYSICIANS AND SURGEONS OF CANADA

The Council, in 1927, authorized monies to be set aside as a loan for organization expenses of the Committee on the formation of a College of Physicians and Surgeons of Canada A meeting was held at Ottawa on February 23rd, 1928, and the expenses of the members

The Editor in presenting his annual report desires to express his indebtedness, and that of the editorial staff, to the many contributors from every province who have enabled the *Journal* to attain, during the past twelve months, an increasingly high standard and present its readers with important papers of practical and scientific interest Canada has of recent years taken an important position in the medical world owing to the excellent scientific work carried out in its universities and hospital laboratories, and to the high standard of the papers presented at its various meetings Especially valuable have been many of the papers which have appeared in our *Journal* during the past year Among the more notable

we may mention those which have dealt with the following subjects: diabetes mellitus and its treatment by insulin, the active principle of the parathyroid gland and its value in tetany, pernicious anemia, its etiology and treatment by liver extract, heart disease in its various forms including coronary thrombosis, gastric and duodenal ulceration, intestinal obstruction, the innervation and development of malignant tumours, and the influence of sunshine and skyshine in the treatment of rickets. Two particularly instructive series of papers have appeared, one on hereditary abnormalities of the eye, and the other on diseases of the blood and blood-forming organs. The subject of anaesthesia and anaesthetics has been fully discussed. Indeed the editorial staff can point to the extensive index of contents for 1927 as a credit to the Canadian profession and to the work accomplished by its members.

In addition to these purely professional papers the *Journal* has also presented to its readers a very excellent series of papers on the History of Pathology. It is also a source of pleasure that we have this year been able to obtain and publish the history of several of our Canadian medical schools. The story of the remaining ones has been promised to the *Journal* in the near future. Here we may state that the editorial board will be very glad to receive and publish the story of the life of any one of the many local leaders in our profession who have made early history in our various provinces, and also any interesting historical item which in any way has to do with members of our profession.

In addition to the regular letters from London and Edinburgh, which we may state have received much favourable comment from many of our readers, letters have been received in this department from France, India, China and Japan. The editorial board would again emphasize its desire to obtain letters for publication in our Correspondence Department from readers in every province discussing local problems of interest, and problems which may affect the well-being of the profession at large.

As the past year was the centenary of Lister's birth this event, on the suggestion of Dr John Stewart, of Halifax, was celebrated not only in every university, but also in every large hospital in the Dominion. The second Listerian oration, delivered by Sir Charles Sherrington at the annual meeting in Toronto, was published as a special issue which contained not only Sir Charles Sherrington's address but also a very interesting address delivered at the centenary celebration in London by Mr Archibald Young, of Glasgow, describing Lister's early work in the wards of the Glasgow Royal Infirmary and the opposition it met with from the hospital authorities. We were also able to publish in this special issue a report by Dr George Rae Gibson, of the Lister Centenary Celebration in Edinburgh, and also a short account of Lister's first visit to America. A reproduction of the coloured portrait of Lord Lister was included, a very pleasing addition to the number made possible through the courtesy of the British Medical Association whose managing editor very kindly loaned the necessary blocks.

The Editor desires to take the present opportunity to express his indebtedness and thanks to the editorial boards of the various provinces and especially to their several chairmen who have not only contributed local news and items of interest, but have assisted in a very marked degree in maintaining a spirit of co-operation and goodwill with the *Journal* in their respective provinces.

It is with much regret that the Editor feels obliged to retire this year from much of the arduous work associated with the editorship. Having passed his fourscore years his friends demand that he take life more leisurely. The *Journal*, however, has been most fortunate in securing the services of Dr Albert G. Nicholls, formerly Professor of Pathology in Dalhousie University, to take charge of this work. Dr Nicholls is particularly well fitted for the editorial task, both by education and experience. His many contributions during the past year have already made him familiar as a writer to all the readers of the *Journal*. We feel therefore certain that his services will prove in every way satisfactory and a great asset to the *Journal*.

The thanks of the Editor are also due to his assistant, Dr MacDermot, who, during the past year, has rendered particularly valuable services. To correspondents both in Canada and abroad, and to all co-workers and contributors the Editor desires to express his indebtedness and thanks.

The whole of which is respectfully submitted

A. D. BLACKADER

Editor

Approved

Reference having been made in the above report to the celebration of the centenary of Lister's birth, it was agreed that the Medical Schools and Provincial Associations of Canada should be asked to co-operate in celebrating "Lister Day" in a fitting manner.

It was resolved that the following cablegram should be sent to Dr Blackader in appreciation of the service he has rendered the Association —

"The Canadian Medical Association in annual convention at Charlottetown expresses by resolution of Council its deep sense of obligation and appreciation to you as the director of the destinies of the *Journal*, and, on this your birthday, wishes you many happy returns."

REPORT OF THE MANAGING EDITOR

Mr Chairman and Members of Council —

Few changes have been made in the technical construction of the *Journal*, the only one of note being a change in the size of type of the headings of original articles, and the running headings at the top of each page. For both a smaller type is used, and the running heading is separated from the subject matter on the page by a thin double line. This change was effected with the April issue, and is felt to be a distinct improvement.

WRAPPERS

The matter of using wrappers instead of envelopes for the mailing of the *Journal* has been carefully gone into as their adoption would mean a saving of some \$200.00 per year. On account of the weight of the *Journal*, however, it is not considered advisable and therefore not recommended. Every single *Journal* weighs one pound and over, and wrappers would probably not afford the same protection from damage in the mails as do the stout envelopes now in use.

EXCHANGE JOURNALS

The *Journals* sent out on an exchange basis number 70, and the *Journals* we receive in return are the leading English, American and Foreign Medical *Journals* which are used by the Editorial Boards in the work of abstracting articles of special value, and for purposes of reference.

COMPLIMENTARY JOURNALS

The free *Journals* mailed each month number 764 and the list comprises officers of the British Medical Association who receive the *Journal* by reason of our affiliation, the presidents of our Canadian universities, the presidents of the Medical Undergraduate Societies of every Canadian university, the Canadian Medical Libraries, Canadian Foreign Missionaries in the Field, and publishers who supply books for review. In this connection it is gratifying to note that for the year there are 403 medical student subscribers, who receive the *Journal* for \$2.50 per annum.

INDEX

It is proposed that commencing with the current year the twelve issues be divided into two volumes in place of

one and an index published with each volume. The twelve issues when bound make too large a book for convenient handling and too heavy for durable binding. By dividing the *Journal* into two volumes and publishing the index semi-annually these difficulties will be overcome. The index will therefore appear in every June and December number.

ADVERTISING

Criticism has been received on one or two occasions in reference to our policy of distributing advertising among the last pages of reading matter in the back section of the *Journal*. On account of the remunerative value, however, of such advertising space any drastic change is not recommended for the time being, for these pages are sold at a higher figure, which aggregates about \$1,000 00 per year over other pages. It is proposed, however, to reduce their number, *as and when feasible*, to four or five instead of the seven or eight.

There are, at present, 121 firms advertising in the *Journal*, which figure does not include classified or single insertions. The receipts from advertising in 1927 exceeded those of 1926 by \$3,078 96.

EDITORIAL BOARD ACCOUNT

The Editorial Board has expended \$5,256 50 in 1927 out of its allowance of \$7,000. The Department has now a credit balance of \$4,117 19. This is made up as follows:

Balance carried forward Dec 31st, 1926	\$2,271 69
Balance carried forward Dec 31st, 1927	1,743 50
Interest to Dec 31st, 1927	102 00
	<hr/> \$4,117 19

All of which is respectfully submitted

ALFRED T. BAZIN,
Managing Editor

Approved

Considerable discussion ensued as to the possibility of reducing the cost of the *Journal* without sacrificing the excellent character of the publication. Dr. Bazin pointed out that, in order that illustrations and cuts may be of any value, it is necessary that a good quality of paper be used in the *Journal*. The question of semi-monthly publication was also considered, but the general opinion was that it is preferable to publish one excellent journal each month rather than an inferior one semi-monthly or weekly.

The question was asked, "Why not allow a special reduced rate to members who are so grouped together in practice as to require only one *Journal* for the whole number?" It was pointed out that membership in the Association is obtainable only upon payment of the \$10 00 fee, the *Journal* being a perquisite of membership. Attention was drawn to the fact that many members who do not require the *Journal* themselves are having their copies sent to medical missionaries.

The following recommendations were submitted to the Executive Committee by the Managing Editor, following a meeting of the Editorial Board held in Charlottetown on June 20th —

1 That Dr. A. D. Blackader, be appointed Editor.
Dr. A. G. Nicholls, Associate Editor, and Dr. H. E. MacDermott, Assistant Editor.

2 That the Editorial Board appropriation for the year 1928 be raised to \$10,000.

3 That the *Journal* be regularly "Copyrighted."

4 That the organization of the Editorial Board be made to conform in some degree to the organization of other standing committees, viz —

That, as heretofore, the Provincial Associations be asked to appoint their representatives on the Editorial Board, that, in addition, the Editor as Chairman, be empowered to select and nominate to the Executive Committee for appointment —

(a) Members of the Central Committee,

(b) Members throughout Canada who are or may be valuable to the *Journal* and who may correspond directly with the Editor.

5 That it is desirable to publish a "complete index" of the *Journal*.

It is recommended that this index shall cover the first twenty-one volumes, i.e., January, 1911, to June, 1928, (21 volumes), the work to be undertaken if and when the Executive considers that funds (estimated cost, \$3,000) are available for the purpose.

Approved

REPORT OF THE COMMITTEE ON ETHICS

Mr. Chairman and Members of Council —

Your Committee on Ethics, of which the nucleus is located in Kingston, has met three times.

No matter was considered of such urgent importance as to require reference to all the scattered members.

The problems laid before the members were —

(1) A complaint of disgraceful conduct on the part of a practitioner. The Committee decided that there was not sufficient evidence to warrant action.

(2) The question of the right of certain drug houses to use papers and extracts published in the *Canadian Medical Association Journal*.

The Committee decided that the rules of the Editorial Board provide for this difficulty.

(3) The question of the use of the name of a member of the Association upon the printed label of a proprietary article.

The Committee decided that there was no special danger connected with the particular case submitted to them, but that the practice was open to abuse, even if permitted in special cases.

All of which is respectfully submitted.

L. J. AUSTIN,
Chairman

Approved

REPORT OF THE COMMITTEE ON PUBLICITY AND PUBLIC HEALTH EDUCATION

Mr. Chairman and Members of Council —

The personnel of this Committee is as follows —

Dr. J. G. FitzGerald, Toronto (*Chairman*),
Dr. Gordon Bates, Toronto,
Dr. J. L. Biggar, Toronto,
Dr. H. C. Boughton, Saskatoon,
Dr. G. D. Porter, Toronto,
Dr. George A. Ramsay, London,
Dr. D. E. Robertson, Toronto,
Dr. A. MacG. Young, Saskatoon.

Several meetings of the Committee have been held during the year, when matters of policy were considered. Acting upon the resolution passed by Council at the last annual meeting, and with the approval of the Executive Committee,

cutive Committee, the Health Service Department of the Association was inaugurated on January first of this year. A series of weekly health articles were prepared by Dr A Grant Fleming, who, without remuneration, has consented to act as Associate Director in charge of the Health Service Department for the current year. These articles were offered to the English and French language newspapers of Canada. As of May first, 184 newspapers, published in Canada having an aggregate circulation of 1,174,443 copies, have accepted the proffered service and are publishing the articles weekly. Each article is submitted to the newspapers in the following form —

HEALTH SERVICE of the CANADIAN MEDICAL ASSOCIATION

Questions concerning health, addressed to the Canadian Medical Association, 184 College Street, Toronto, will be answered by letter. Questions as to diagnosis and treatment will *not* be answered.

The newspapers in which this popular health educational material appears, are published in every Province of the Dominion. Newspapers in the larger cities from coast to coast, as well as those in the small towns, have gladly accepted the service thus rendered by the Canadian Medical Association.

A large number of letters of enquiry have been received and have been answered by the Associate Director of the Health Service, on behalf of the Association. The original letters and the replies thereto have also been read and considered by the General Secretary and by the Chairman of the Committee. This has entailed a very considerable volume of work. In this connection, the Committee, and through it the Association, is deeply indebted to Miss McQuarrie of the Montreal Tuberculosis and General Health League, for much assistance in the preparation and translation of replies to those correspondents whose enquiries, written in French, are replied to in that language.

Health Service articles of the Association have regularly appeared in a number of newspapers in the Province of Quebec. Included among these, is the newspaper with the largest circulation of any paper printed in the French language.

When the Health Service Department was organized, it was anticipated that a grant would be received to provide for its support for the year. Subsequently, however, it was learned that this contribution would not be forthcoming and a very modest appropriation of two thousand dollars was made by the Executive Committee to permit the Department to inaugurate its work. As has already been indicated a very heavy task was generously assumed by Dr A Grant Fleming, who declined to receive an honorarium for his services when the Department was organized. The Committee desires on behalf of the Association to express its appreciation of the splendid work done by Dr Fleming.

Since the work of this Committee and that of the Committee on Public Health and Periodic Health Examination is cognate, it would seem advantageous to consider the question of constituting a new Committee which would embrace the functions of all three. Such a combined Committee would probably be in a better position to correlate much of the work which at present is somewhat artificially divided and dealt with by three separate groups instead of being allocated to a composite and representative committee competent to undertake work bearing upon the problems of public health, publicity and popular health education, as well as periodic medical examinations.

All of which is respectfully submitted

J G FITZGERALD,
Chairman

Approved

In presenting the above report, Dr FitzGerald called attention to the valuable assistance rendered this Department by Dr A Grant

Fleming, McGill University, and the Montreal Anti-Tuberculosis and General Health League

REPORT OF THE COMMITTEE ON PUBLIC HEALTH

Mr Chairman and Members of Council —

Your Committee on Public Health for 1927-28 is made up of the following —

Quebec - - - - -	Dr J Roddick Byers, Westmount, Dr H B Cushing, Montreal, Dr H S Shaw, Outremont, Dr W T B Mitchell, Montreal, Dr A H Desloges, Montreal, Dr J E Dubé, Montreal, Dr A Grant Fleming, Montreal, (Chairman),
Ontario - - - - -	Dr J G FitzGerald, Toronto, Dr Geo D Porter, Toronto,
British Columbia - - -	Dr H W Hill, Vancouver, Dr F T Underhill, Vancouver,
Saskatchewan - - - -	Dr M M Seymour, Regina, Dr R M Bow, Regina, Dr Arthur Wilson, Saskatoon,
New Brunswick - - -	Hon Dr Wm F Roberts, St John, Dr William Warwick, St John,
Alberta - - - - -	Dr L S Mackid, Calgary, Dr Geraldine Oakley, Calgary,
Nova Scotia - - - -	Dr W H Hattie, Halifax, Dr A C Jost, Halifax,
Manitoba - - - - -	Dr A J Douglas, Winnipeg, Dr D A Stewart, Ninette,
Prince Edward Island	Dr I J Yeo, Charlottetown

Your Committee has deemed it advisable to place before the Association, for consideration, the question of Housing. In the prevention of disease and the promotion of health, a good environment plays a most important part. Whilst attention has swung away from environment because of the newer understanding of the importance of the individual, environment is of essential importance in making possible the carrying out of personal hygiene.

Throughout Canada, there are groups of citizens interested in the subject of town planning and housing. It seems desirable that the Association be on record, for the information of such groups, as to the principles of which they approve.

Your Committee, in submitting these principles for endorsement, has indicated the main points which should be covered, because of their relationship to health, in legislation dealing with the subject, and has not attempted specific definitions. It is appreciated that education must precede legislation, and that the only legislation which is of value is that which represents public opinion.

The following principles are submitted —

1 That every town or city should have town planning and housing legislation, with provision for its enforcement. That whatever provincial legislation is necessary to make such town planning and housing effective should be passed by the various Provincial Legislatures, and such town planning should provide for open spaces, playgrounds and residential areas.

2 That Provincial Health Departments pass regulations governing the construction of new dwellings and the remodelling of old dwellings throughout each province to ensure healthy homes in both urban and rural areas. Under a Provincial Town Planning and Zoning Act, the Provincial Health Department should enact housing regulations suitable to the various zones created. All plans for new dwellings and for the remodelling of old dwellings should be passed upon by the local sanitary authority before a permit for building is issued.

3 That every dwelling be built on a dry site, with the long axis of the dwelling north and south, thus allowing for the entrance of sunlight to every room, and that it be weather-proof and damp-proof.

4 That every dwelling have yard space and be not over-crowded by other buildings.

5 That every dwelling, where there is a public water-supply within reasonable distance, have such supply introduced into the dwelling

6 That every dwelling, where there is a public water-supply and sewers within reasonable distance, be provided with proper sanitary conveniences—water-closet, bath, wash-basin and kitchen-sink

7 That every dwelling have a separate kitchen with cooking facilities, and a fly-proof, ventilated food and milk-safe

8 That every dwelling have provision for its adequate and safe heating and artificial lighting, and that the use of gas stoves for cooking and heating be properly safeguarded

9 That no dwelling house have outside porches, platforms, balconies or stairways so located or constructed as to interfere with or diminish the light or ventilation required

10 That every room in every dwelling be of adequate size with provision for lighting and ventilation

11 That every room in every dwelling have at least one window of proper size, opening directly on a street, yard or court of adequate dimensions

12 That alcove rooms be considered as separate rooms, as to size, requirements of windows and provision for ventilation

13 That the number of persons per room per dwelling be limited in order to prevent over crowding

14 That no person be allowed to sleep or live in cellar rooms

15 That, preferably, no person be allowed to sleep or live in basement rooms. If such be allowed, such rooms should be adequately ventilated and lighted and, in addition to all this, the Sanitary Authority should be given power to pass finally on conditions

16 That dwellings built for and intended as one-family dwellings be not otherwise used as multiple dwellings, unless alterations be made that render them suitable for use as multiple dwellings

Your Committee would recommend, subject to their endorsement by the Association, that a copy of these principles be forwarded to all provinces

In regard to the subject referred by Council to the Committee for consideration—that is, the drawing up of a scheme of Public Health Insurance—your Committee advises that the desirability of taking further steps in this matter be determined by Council, after hearing the report of the sub-committee which was to be appointed to study the whole question of health insurance

Your Committee would urge that this study be continued, and that, through the sub-committee's reports to Council and any special reports, the profession be kept informed as to what is being done elsewhere in this field

All of which is respectfully submitted

A. GRANT FLEMING,
Chairman

Considerable discussion ensued with reference to Clause 3 of this report and it was finally agreed that it be changed to read as follows—

"That every dwelling be built on a dry site, with (where possible) the long axis of the dwelling north and south, thus allowing for the entrance of sunlight to every room, and that it be weather-proof and damp-proof"

It was also agreed that the paragraph, "Your Committee would recommend all provinces" should be changed to read as follows—

"Your Committee would recommend, subject to their endorsement by the Association, that a copy of these principles be forwarded to the Provincial Governments and to such other agencies as may be designated by the incoming Executive Committee"

In the discussion on this report it was recommended that a copy of the report be sent to each of the Provincial Boards of Health, asking them to take action to see that houses reported as unsanitary be either destroyed or put in a sanitary condition. It was also recommended that the report *in toto* be used for publicity purposes by the Committee on Publicity and Public Health Education

The report, as amended, was approved

REPORT OF THE COMMITTEE ON PERIODIC HEALTH EXAMINATION

Mr. Chairman and Members of Council—

Since the last annual meeting of the Canadian Medical Association, at which a progress report was given, your Committee has completed a "Manual of Guidance" and "Record Form" for physicians desiring to undertake Periodic Health Examinations

This Manual and this Record Form have been submitted to a number of physicians and surgeons interested in their publication, and in their present form, the Manual and Record Form represent a more or less united opinion of this group

The Manual will be published as a booklet, in which the pages will be 5" x 8", and the Record Form (half size) will be included therein. Additional forms will be printed in full size—one to be enclosed in each booklet for the use of practitioners

Arrangements have been concluded with the Federal Department of Health, by which they will not only print the volume but likewise will distribute one copy to each physician in Canada (irrespective of whether he is a member of the Canadian Medical Association or not)

The Canadian Medical Association can, moreover, have a plate made and print further copies of the Record Form for use by the profession. These forms will, of course, be issued to the profession at a reasonable rate, and it is expected that all physicians who use the form will be willing to pay for a supply

The technique of popularizing Periodic Health Examinations has been discussed by the Committee, as well as with other members of the profession

It is hoped that co-operation with the Insurance Companies may be effected to facilitate the dissemination of the idea. For the present, we believe that the distribution of the Manual and Form is in itself a satisfactory beginning, and it would be well to await the response from the profession before attempting more detailed plans

In conclusion, we suggest that the Canadian Medical Association express its indebtedness to the Federal Department of Health for its co-operation and valued assistance

All of which is respectfully submitted

C. F. MARTIN,
Chairman

Supplementing the above report, the General Secretary outlined the following plan for the carrying out of periodic health examinations by the Canadian Medical Association, in co-operation with the insurance companies of Canada—

The Canadian Medical Association offers to the insurance companies of Canada a plan whereby their policy holders will be given a complete physical examination, the policy holder, in each instance, selecting his own doctor. For this examination, the insurance company will pay the Canadian Medical Association a fixed fee

We in turn will pay the examining physician, and retain a certain amount for overhead

After receiving the list of policy holders contracted for by the insurance company, a letter is written to the policy holder asking him to nominate the doctor whom he would like to have examine him. Upon receipt of this information, a tripartite form is sent to the doctor, with instructions that he get in touch with the policy holder named and have the examination completed. It will be noted that this form is in three parts. Part one is the record of the examination, details of which are only known to the policy holder and the doctor. It is most important to stress the point that no information regarding the examination is imparted to any other person or institution. The same confidential relationship exists between the doctor and the policy holder as now obtains between the doctor and his patient. The report may either be retained by the physician, or given to the policy holder, as is mutually agreed upon by these two persons.

Section 2 is the physicians report form to the Canadian Medical Association, merely stating that the examination has been carried out. Upon receipt of this voucher, the doctor will be paid. This will also be the voucher upon which we will collect from the insurance company.

Section 3 is the report from the policy holder, which indicates to us whether or not he was satisfied with the examination. This report offers the one avenue of information to the Canadian Medical Association as to how the work is being done.

Obviously, the whole scheme involves careful preparation and propaganda, whereby both the physician doing the work and the policy holders to be examined will be made thoroughly familiar with what is involved.

OUTSTANDING FEATURES

- 1 The policy holder names his own doctor
- 2 The examination form will be sent to the doctor so named
- 3 The responsibility rests with the doctor to approach the policy holder
- 4 The policy holder's report makes it possible for us to follow the work. The doctor's report is not lengthy, and is merely a voucher upon which we pay him
- 5 The plan makes it possible for organized medicine, through the practising physicians of Canada, to offer to the insurance companies of Canada a service which will fill a long felt want
- 6 If Council authorizes the Association to initiate this work, we have every reason to believe that at least some of the insurance companies are prepared to enter into a contract with us
